changes are frequently seen in coronary disease, in advanced arteriosclerotic heart disease and in decompensated hearts.

(b) In the second division, numerous variations and changes in the contour of the individual waves are of diagnostic importance. Four variations in the ventricular waves are characteristic of known cardiac disorders.

1. In the so-called nervous or irritable hearts<sup>7</sup> a sharp peak appears on the crest of the ventricular wave just preceding systole.

2. In hyperthyroidism,<sup>15</sup> particularly that due to exophthalmic goiter, the waves are increased in ampli-

tude and have a short total period of systole. In contradistinction to other types of heart disease, the last part of the systolic phase is the fastest which makes the ventricular waves biconvex.

Fig. 4.—Area of cardiac infarction demonstrated on kymogram: Areas of cardiac infarction can occasionally be identified. They are recognized as areas without motion or of greatly diminished motion (frames 1 and 2) in presence of ample movement in the adjacent frames. Ventricular waves are low and poorly defined, indicating marked myocardial impairment.

3. In myxedema<sup>10</sup> the ventricular waves are low and flat and, from our studies, appear to be characteristic of this disturbance.

Fig. 5.—Syphilitic aortitis: The characteristic pathologic lesion in syphilitic aortitis is a destruction of the elastic fibers. When the disease has advanced to this extent, the waves over the ascending aorta become large and almost pyramidal, owing to the loss of the resilience of the aortic wall. These waves are characteristic and serve as a differential diagnosis between syphilitic and arteriosclerotic widening of the aorta.

4. In cases of rheumatic heart disease with mitral insufficiency,<sup>16</sup> fat truncated waves are seen over the lower left ventricle. Lesions affecting the ascending

aorta and semilunar valves produce very striking kymograms. In aortic regurgitation the aortic waves show a great increase in amplitude and a prompt retraction as part of the blood rushes back into the ventricle. The wave is analogous to that of the Corrigan pulse.

With stenosis of the semilunar valves the outward thrust of the aorta becomes an oblique line because it fills slowly as the blood is forced through the narrowed orifice. The ventricular systole is likewise slower.

Syphilitic aortitis<sup>13</sup> produces a kymogram as characteristic as its pathology (fig. 5). The waves over the ascending aorta are pyramidal, are increased in amplitude and retract quickly. The waves over the descending aorta are unchanged. The presence of these waves over a widened aorta makes a "grand stand" differential diagnosis from arteriosclerotic changes, in which the waves are unchanged or even decreased in amplitude.

The kymographic analysis of aneurysms<sup>11</sup> is complicated and will not be discussed in this paper other than to say that this method is another aid in the differential diagnosis between aortic aneurysms and mediastinal tumors.

We have been unable to recognize any consistent change in the kymograms of patients with hypertension and arteriosclerotic heart disease.

Of the arrhythmias, "extrasystoles" and pulsus alternans produce striking kymographic records. Other types of cardiac irregularities<sup>17</sup> have been reported, but we have been unable to identify them accurately.

#### CONCLUSIONS

1. Roentgen kymography is an objective and accurate method for graphically recording the physiologic movements of an organ or structure on a single x-ray film.
2. Kymographic waves are the records of the form, amplitude, direction, speed, frequency and time relationships of movements occurring at equally spaced points on the border of an organ.
3. The procedure is simple, practical, inexpensive and of considerable clinical value.
4. Kymography is an effort to fill the gap between roentgenoscopy and roentgenography and is not designed to replace either.
5. Both the kymogram and the standard chest film portray the size and outline of the heart, but only the kymogram gives a record of the movement of the heart chambers and great vessels.
6. Diagnostic kymographic tracings occur in certain types of heart disease, notably aortic regurgitation, aortic stenosis, syphilitic aortitis, hyperthyroidism, myxedema, constrictive adhesive pericarditis, tuberculous pericarditis, pleuropericardial-diaphragmatic adhesions, aneurysms of the ascending aorta, cardiac infarction, "irritable" heart and a few arrhythmias. These tracings also supply information concerning the tonicity of the heart muscle that is of prognostic importance.
7. Kymography is another aid in the differential diagnosis between aortic aneurysms and mediastinal tumors.
8. Roentgen kymography is a new method for the investigation of physiologic movement in the field of pure research.

#### ABSTRACT OF DISCUSSION

DR. M. C. SOSMAN, Boston: This apparatus can be made in one's own carpenter shop at a total cost of from \$30 to \$35. The very expensive apparatus is not necessary for most of the work. If one wants very accurate gadgets on one's machine it will cost more money. (Details can be found in the paper by Dr. S. E. Johnson, *Surg., Gynec. & Obst.* 61:169 [Aug.] 1935.) The method is an extremely valuable addition to the methods already in use. It gives one information not obtainable in any other way. Part of the information can be picked up by watching the heart movements under the fluoroscope. A large part, however, is too fast or too detailed to pick up, but one can get it in detail on the kymograph film. As an example of the value of this method I will mention a case in which a large tumor extended out from the left hilus. There were enlarged cervical lymph nodes, which had been increasing in size gradually in the past few months. The obvious diagnosis was lymphoma. But on the kymogram not only the pulsation of this mass but an abnormal pulsation was demonstrated. It pulsed more than either the heart shadow or the aorta, and a test was tried which I believe is practically pathognomonic of aneurysm of the pulmonary artery. That is to take two kymograms with different phases of intrathoracic pressure. The first film was made with the patient's chest full of air trying to exhale against a closed glottis, in order to squeeze as much blood out of the heart as possible. There was a barely perceptible pulsation of this mass. The other film was made after letting the breath out, and the pulsation was markedly increased. I feel that this rules out any solid tumor of the mediastinum or of the hilus lymph nodes. It makes it practically certain that there exists a very thin-walled pulsating mass. The only condition answering that description is an aneurysm of the pulmonary artery.

#### TRANSURETHRAL OPERATIONS

##### CHANGING CONCEPTIONS DURING THE PAST FIVE YEARS

GERSHOM J. THOMPSON, M.D.  
ROCHESTER, MINN.

Prior to five years ago there were few physicians who believed that much could be accomplished by transurethral operation on the enlarged prostate gland. Caulk, by virtue of long persistence and perseverance, was the first urologist to find that the results obtained with this method in cases in which the prostate gland was quite large were as good as those obtained with operation performed for the removal of small median bars or contracture of the vesical neck. Unfortunately, however, it was none too easy for the large majority of urologists to visualize the operative field with Caulk's punch and, in addition, many were frightened by the severe hemorrhage and postoperative reaction that often followed their unskilful maneuvers. It was therefore not until Stern invented the electroresectoscope, which later was modified by Davis and McCarthy, that most urologists could be induced to attempt transurethral operations except in rare instances.

The stimulus to this type of operation, resulting from the introduction of the improved Stern-McCarthy resectoscope, can well be estimated by the fact that approximately 2,500 of these resectoscopes have been manufactured and distributed. It seems likely that many who purchased these instruments did so without previous cystoscopic experience that would justify the investment. There are no doubt more than 2,500 physicians who possess the ability to catheterize the ureters or inspect the interior of the bladder. On the other

hand, it is my opinion that few physicians, other than urologists, have had training in posterior urethral endoscopy which will enable them even to recognize the various types of prostatic deformity that are encountered, let alone attempt their removal. Increased mortality and morbidity might therefore be expected when transurethral operations are performed in spite of this lack of training and, as is well known, these expectations have been more than adequately fulfilled.

It is not my purpose, however, to dwell on these facts; rather, I would call attention to various developments in transurethral operations that have permitted their application in lesions of the bladder and urethra that do not necessarily accompany prostatic hypertrophy. Familiarity with the use of the resectoscope has naturally led to its employment for the correction of other pathologic entities. In addition, all types of operative cystoscopy have been stimulated and instruments other than the resectoscope have been used more often and to greater advantage than they were previously. I wish to emphasize at the outset that no claim is being made to priority in the development of any of these procedures.

Fig. 1.—Method of removing epitheliomas of the bladder with Stern-McCarthy resectoscope.

der and urethra that do not necessarily accompany prostatic hypertrophy. Familiarity with the use of the resectoscope has naturally led to its employment for the correction of other pathologic entities. In addition, all types of operative cystoscopy have been stimulated and instruments other than the resectoscope have been used more often and to greater advantage than they were previously. I wish to emphasize at the outset that no claim is being made to priority in the development of any of these procedures.

#### TUMORS OF THE BLADDER

Before the advent of the resectoscope the complete destruction of vesical epitheliomas of a diameter much greater than 1 cm. involved repeated electrocoagulation of the growth at intervals of a week to a month. Very few urologists felt it wise to remove the tumors with a rongeur or operating forceps, because they feared the onset of uncontrollable hemorrhage. The cutting loop of the resectoscope (fig. 1) has been found a very satisfactory instrument for the rapid removal of many tumors of a pedunculate or relatively noninfiltrating type (fig. 2). The bulk of the growth can be rapidly removed (fig. 3) with the cutting current, following which the pedicle or base can be thoroughly destroyed by electrocoagulation. Often it is expedient to remove a portion of an unusually papillary tumor with forceps passed through the direct vision cystoscope and rely on the resectoscope to trim the base.

It is technically more difficult to remove those tumors which occur high in the lateral walls or dome of the bladder than it is to remove those situated in the base or near the ureteral orifices. I have found it easier to keep the cutting loop in a fixed position in relation to the sheath of the instrument during most of its excursion, and to drag the loop through the growth by moving the entire instrument rather than to employ the reciprocating mechanism. A tumor that lies in close proximity to the ureteral orifice or in fact overlies it can be excised with apparent impunity, for none of the patients have suffered from renal colic postoperatively. In several instances in which the ureteral meatus has been cut away, almost perfect healing followed, for cystoscopy months later disclosed a practically normal appearance. Pyelectasis, which was apparent prior to operation in such cases, has been observed to disappear completely, as evidenced by urograms made in the course of reexamination.

In some cases, particularly in those in which microscopic study reveals a high grade of malignancy, it is well, after removal of the tumor, to implant radon seeds in the underlying vesical wall. In certain cases in which the extent of the lesion or the general condition of the patient has precluded radical surgical removal, this method, combined with subsequent roentgenotherapy, has resulted in remarkable palliation and in some instances it apparently has resulted in a cure (fig. 4).

At the Mayo Clinic during the four years 1932 to 1935 inclusive, tumors have been destroyed in 191 cases by the methods outlined, practically always at one sitting. The results to date from such treatment have been, on the whole, very gratifying, although sufficient time has not elapsed to warrant final conclusions concerning the efficacy of the method.

#### VESICAL CALCULI

Litholapaxy has for many years been advocated for the removal of calculi in the urinary bladder. However, it was not, as a matter of fact, advised in cases in which other pathologic changes would subsequently necessitate suprapubic surgical attack. For this reason, only a minority of the patients encountered were given the benefit of a procedure which in skilful hands would save them many days of hospitalization. The presence of a considerably hypertrophied prostate gland was always deemed a contraindication to litholapaxy. I have previously reported a series of cases in which I was able to crush and remove large calculi (fig. 5) and under the same anesthetic resect the obstructing por-

Fig. 2.—Preoperative intravenous cystogram showing filling defect produced by a tumor that was subsequently removed by transurethral operation; cystoscopy one year later disclosed no recurrence.

tion of the prostate gland.<sup>1</sup> The greatest amount of tissue removed in any case was 47 Gm. It is important that the litholapaxy be performed rapidly; hence a lithotrite of the Bigelow type is used by preference. With this instrument the stone can usually be engaged readily and crushed safely if one follows the technic

1. Thompson, G. J.: Simultaneous Litholapaxy and Prostatic Resection, *Proc. Staff Meet., Mayo Clin.* 10: 689-692 (Oct. 30) 1935.

outlined in figure 6. As a general rule, it is best to crush the stone prior to prostatic resection; but if the lithotrite cannot be passed easily beyond the prostatic enlargement it may be necessary to perform prostatic resection first.

During the past four years, 161 patients with vesical calculi have been treated by conservative transurethral methods. Rather large calculi have been removed in many of the cases; in fact, during the entire year 1935

neck of the diverticulum in both instances was small, but fortunately it could be readily dilated. After the stone is drawn into the bladder it is crushed in the usual manner. I recognize that this procedure does not abolish the diverticulum, although I have noted in many cases that vesical diverticulitis often disappears and the urine becomes clear after removal of the obstructing portion of the prostate gland. Cabot and I will give a complete report on this subject at a later date.

#### URETERAL CALCULI

Bumpus and I,<sup>2</sup> in 1930, reported a clinical study of 1,001 cases of ureteral calculi; in 60.7 per cent of cases in which a calculus occurred in the lower part of the ureter it was removed by transurethral methods. In most of the cases in that series more than one attempt was made before the stone was obtained, and many times it was not passed until a number of days subsequent to manipulation. During the years 1932 to 1935

Fig. 3.—Tumor tissue removed by transurethral operation (weight 37 Gm.).

it was necessary to perform suprapubic lithotomy in only four instances. The saving in hospital expense to the patient between two-stage lithotomy and prostatectomy as compared with one-stage litholapaxy and prostatic resection is remarkable.

Fig. 4.—Radon seeds implanted in vesical wall following removal of an epithelioma, grade 4. Almost three years has elapsed without recurrence. Apparent migration of some of the radon seeds may be noted.

During the past year I have been able several times to remove calculi from vesical diverticula. In two cases the stones were too large to grasp with forceps and hence it was necessary to dislodge them from the diverticulum into the bladder by using a loop of banjo wire, which was encircled around the stone. This was done with a direct vision cystoscope (fig. 7). The

Fig. 5.—Large vesical calculus removed by litholapaxy; prostatic resection was done under the same anesthesia.

inclusive, stones have been removed from the ureter by transurethral methods in 180 cases; in the very large majority the first attempt was successful, the calculus being removed at the time of the operation, either by engagement with an extractor or by the safer method of enmeshing it with multiple catheters.

In my experience a stone dislodger or extractor will be found most satisfactory in those cases in which a very definite ureterectasis exists, for the instrument can be introduced into the enlarged ureter easily and can be manipulated freely, which fact aids tactile sensation. Through alternate expansion and contraction of the instrument it is often possible to feel the approximate position of the stone. Ureteral catheters, on the other hand, are most valuable in those cases in which there is little or no ureterectasis. An attempt to force an extractor into a small ureter may result in perforation and certainly will cause severe reaction. One should prefer to insert two or three catheters alongside

2. Bumpus, H. C., and Thompson, G. J.: Stones in the Ureter, *Surg., Gynec. & Obst.* 50: 106-109 (Jan.) 1930.

the stone and leave them in place for from forty-eight to seventy-two hours. Twisting the catheters at that time will often be more profitable than doing so immediately after they are placed.

Ureteral stone extractors or dislodgers of any type generally produce much more trauma to the ureter than do ureteral catheters. Hence I have felt that all attempts to remove stones with these instruments should

Fig. 6.—Diagrammatic representation showing three positions of the lithotrite during lithotripsy. Depressing the base of the bladder will cause the stone to gravitate quickly to the jaws of the instrument; after the stone has been grasped, rotation of the lithotrite will make certain that the vesical wall has not also been included. The stone is then crushed.

be made in the hospital. In order to guard against severe systemic reaction from ureteritis and pyelonephritis, manipulation should be done in a strictly aseptic manner, and drainage by means of the ureteral catheter is deemed necessary for several days following unless the extraction has been unusually easy.

#### PROSTATIC CALCULI AND PROSTATITIS

Attention has been previously called to the value of transurethral procedures for the removal of prostatic calculi.<sup>3</sup> These calculi often do not produce symptoms. Hence I have practically always disregarded their chance finding by routine roentgenologic study. However, when either for local or for focal reasons it is essential to reduce or eliminate the prostatitis which generally is found in association with prostatic calculi, it is not a very difficult task to remove them by transurethral incision. I prefer to use the Collings knife, for one can gage the depth of the incision, making it no deeper than is actually necessary to expose the nests of stones. Such operations must always be done with thorough recognition of the fact that the procedure is a minor one as far as the patient is concerned. Lack of caution might easily result in a major complication, if not in death.

In eight cases I have incised acute prostatic abscesses with the Collings knife, thus evacuating a large pocket of pus through the urethra. This I believe is a much better method than is the old practice of puncturing the abscess with a urethral sound, for one can make a wide incision and if the pocket is multilocular divide any

septums that might interfere with free drainage. The immediate relief from pain is very striking and in no instance has cystitis or pyelonephritis prolonged the convalescence; this provides further evidence that the bladder is as a rule very resistant to infection.

The treatment of chronic abscesses of the prostatic ducts by transurethral saucerization or incision, which promotes free drainage, has also been described in a former article.

#### URINARY OBSTRUCTION AMONG WOMEN AND CHILDREN

Congenital obstruction of the posterior urethra or vesical neck among boys is a clinical entity that has been recognized for years. Ten such cases have been encountered at the clinic in which it has been possible to relieve the obstruction by actual removal of tissue with the baby punch or by incision of the posterior urethra or vesical lip with the cutting current applied through a thin wire electrode. The preoperative and postoperative urograms in such a case are shown in figure 8. The patient in this instance was enabled to empty his bladder completely, in contrast to 20 ounces (590 cc.) of residual urine that was present prior to operation. The remarkable effect on general health was evidenced by a gain of approximately 60 pounds (27 Kg.) during the ensuing two years.

Eleven women have had their ability to urinate restored by division of a portion of the sphincter with the Collings knife or by removal of sections of tissue from the vesical neck with the resectoscope. I<sup>4</sup> have previously reported one of these cases in which the patient was 73 years of age and had been unable to void for many months. The removal of five pieces of tissue restored normal vesical function. These twenty-one instances of urinary obstruction among women and children will be described in detail at some future date.

#### NEUROGENIC VESICAL DYSFUNCTION

Braasch and I<sup>5</sup> have reported a group of cases of atonic bladder. In several cases a diagnosis of atypical cord bladder had previously been made even though no abnormal alteration in motor or sensory nerve supply could be found by any of the ordinary methods of neurologic examination. An imbalance of the nerves controlling micturition might nevertheless have existed in these cases, thus resulting in a spasticity of the vesical sphincters which finally led to actual, although slight, hypertrophy. Whatever might be the mechanism that produced urinary retention, transurethral resection of a portion of the internal sphincter restored normal vesical function.

Fig. 7.—Withdrawal of a stone from a vesical diverticulum with a loop of wire; the orifice of the diverticulum must be pliant and easily dilatable.

3. Thompson, G. J., and Cook, E. N.: Chronic Prostatitis and Prostatic Calculus: Treatment by Incision with the Electrocautery, *J. A. M. A.* 104: 805-807 (March 9) 1935.

4. Thompson, G. J.: Transurethral Operations for Relief of Dysfunction of the Vesical Neck in the Female, *Proc. Staff Meet., Mayo Clin.* 10: 598-600 (Sept. 18) 1935.

5. Braasch, W. F., and Thompson, G. J.: Treatment of the Atonic Bladder, *Surg., Gynec. & Obst.* 61: 379-384 (Sept.) 1935.

Since then, one patient has been seen who definitely had a cord bladder which resulted from a transverse myelitis attributable to fracture of the spinal column. For many months subsequent to the injury he had urinary incontinence, but he finally regained full control of his urinary sphincters and was able to urinate with great effort and force exerted with the abdominal muscles. He has never regained full use of his legs and spends a great deal of time in bed. Cystoscopy disclosed a relaxation of the prostatic urethra, which was regarded as a typical result of injury to the spinal cord, but the internal sphincter was definitely spastic and hypertrophied. Division of this thickened sphincter with the resectoscope has made it possible for the patient to urinate without effort and to empty his bladder completely; in addition, there has been no loss of urinary control.

I am of the opinion that cases of this type will occasionally be encountered and that the condition can be definitely benefited by transurethral operation. A careful selection, however, seems necessary and promiscu-

the clinic for transurethral resection, belonged to this age group. Only three of these patients died, a mortality of 2.7 per cent.

Another group of patients who have been relieved by transurethral operation is that in which renal function has been seriously impaired by the long standing obstruction and resultant back pressure. The value for urea often is fixed at more than 100 mg. per hundred cubic centimeters of blood, even after prolonged periods of drainage of the bladder through a urethral catheter or suprapubic tube. In spite of this severe renal injury, prostatic resection can be performed in these cases with only slight risk. It is essential, however, that complications be avoided.<sup>7</sup> Thorough resection followed by very careful postoperative attention to guard against hemorrhage and infection is therefore extremely important.

#### MORTALITY

There has been no mortality from any of the transurethral procedures described, except in the group of cases in which prostatic resection was performed. Of 1,987 patients subjected to transurethral resection for either benign or malignant involvement of the prostate gland during the years 1932 to 1935 inclusive, only fourteen died, a mortality of 0.70 per cent.

#### SUMMARY

During the past five years the great value of transurethral operations for the relief of various disorders of the bladder, urethra and prostate gland has become apparent. Conservative transurethral procedures can now be employed in many cases in which open surgical operations formerly were required. Elderly patients who, because of the risk involved, declined to submit to other types of operation are reporting to the urologist for transurethral operation and are being relieved of symptoms with minimal risk.

#### ABSTRACT OF DISCUSSION

DR. GEORGE R. LIVERMORE, Memphis, Tenn.: I wish to endorse Dr. Thompson's use of the cutting current through the resectoscope loop for the rapid removal of many tumors of the bladder, as I have found it most satisfactory for this purpose. My experience coincides with his with regard to the freedom from cicatricial contracture even when the ureteral meatus is involved. I rather doubt the wisdom of his advice, however, with regard to performing litholapaxy and prostatic resection at the same sitting. There is usually some reaction following litholapaxy, especially when copious irrigation and perhaps removing larger fragments with cystoscopic forceps are necessary, and this, added to that of resection, may be sufficient to add to the mortality. No doubt he selects his cases and in this way is able to limit his mortality. I am in favor of the cystoscopic removal of ureteral calculi and feel that it should be attempted and persisted in so long as the patient's condition and the kidney functional output will permit. Both my ureteral stone dislodger and ureteral dilator have aided me in prompting the passage of calculi. Dr. Thompson's caution as to their use is especially sound. Transurethral resection is the greatest urologic advance since Hugh Young showed the value of preoperative preparation for prostatectomy.

DR. HERMAN L. KRETSCHMER, Chicago: Dr. Thompson's paper illustrates the general trend away from open surgery in favor of transurethral surgery in the treatment of various lesions in the genito-urinary tract. He is to be commended for again calling attention to the importance of a thorough knowledge of the normal and pathologic anatomy of the deep urethra when these various forms of instrumentation are undertaken. My experience in the treatment of bladder tumors by means of the resectoscope is in close accord with his experi-

Fig. 8.—Urograms in a case of congenital obstruction of the vesical neck; *a*, preoperative urogram showing marked hydronephrosis and hydroureter; patient had uremia; *b*, postoperative urogram made two years later and showing marked reduction in pyelectasis; patient's health excellent.

ous operation on all patients suffering with cord bladder would no doubt result in permanent incontinence in the majority, as well as other harmful effects.

#### RESECTION OF THE PROSTATE GLAND

Prostatic resection has been a boon to many men during the economic depression of the past five years. The short stay in the hospital has enabled hundreds of them to afford operative relief. Of greater interest to me, however, is the fact that this operation, because of its distinctly lessened morbidity and mortality, has encouraged men to seek relief who formerly suffered the tortures of an obstructed urinary stream between intervals when they resorted to the use of a catheter. The mortality of prostatectomy in cases in which patients are more than 75 years of age has always been high. The patient as well as the physician has recognized this fact and as a consequence has elected in years gone by either to neglect his condition or to rely on nonoperative treatment rather than submit to prostatectomy. As evidence of this fact, I shall compare a few figures. Hunt,<sup>6</sup> in a report of 1,000 cases in which prostatectomy was performed, found that only 3.1 per cent of the patients were 75 years or more of age. During the year 1935, on the other hand, 109 patients, or 15.7 per cent of 695 patients who came to

6. Hunt, V. C.: Benign Prostatic Hypertrophy: A Review of One Thousand Cases, *Surg., Gynec. & Obst.* 46: 769-773 (June) 1928.

7. Thompson, G. J.: The Prevention of Complications of Transurethral Prostatic Resection, *Urol. & Cutan. Rev.* 38: 847-851 (Dec.) 1934.

ence. Large papillomas can be removed in one or two sittings; this is a distinct advance over their destruction by means of electrical fulguration. The question of the treatment of stone associated with prostatic obstruction depends on several factors: the size of the stone, the presence or absence of infection, and the skill of the surgeon in using the lithotrite. In cases of small stones with but little or no infection, the resection and the litholapaxy are carried out at the same time. If the stone or stones are large they are crushed first, the bladder is drained with an indwelling catheter and the resection is carried out a few days later. If the stones are large and the infection marked, a suprapubic cystostomy is done first and the resection is done later after the bladder infection has cleared up. In my opinion after-care is just as important as is the preoperative treatment. I have changed my views regarding the institution of preoperative drainage. Preoperative catheter drainage is not carried out if the patient has a normal renal function, not more than 6 ounces of residual urine, if the urine is clear or contains only a few pus cells, and if the physical examination shows the heart and lungs to be in good condition. A recent survey showed an interesting fact regarding the frequency of cardiac cases that were sent in for resection. In the days of surgical prostatectomy about 35 per cent of the patients had heart lesions. A recent survey showed that about 65 per cent have cardiac disorders. This is a relatively high incidence and, I think, is due to the fact that many more so-called bad risk cases are sent in for resection that were formerly sent in for prostatectomy.

DR. WILLIAM J. ENGEL, Cleveland: The widespread use of prostatic resection in the past five years has been a large factor in reawakening interest in transurethral operations of other types. It not only increased the appreciation of the possibilities of cystoscopic surgery but has made urologists more expert in the use of urethral manipulations. Transurethral surgery, where applicable, has three indisputable advantages over open operation: (1) It lowers the mortality rate, (2) it saves time for the patient, and (3) it saves money for the patient because of a shorter period of hospitalization and convalescence. There may be those who have been misled to believe that it is easier, but from experience with both the open operation and the transurethral method in similar lesions I am convinced that the transurethral operation is in most instances decidedly more difficult for the surgeon, so that the advantage accrues solely to the patient, where it belongs. The cystoscopic surgeon must have more patience, exercise greater care, and have a more intimate knowledge of the bladder and urethra in health and in disease. The intravesical excision of certain bladder tumors has been an outgrowth of prostatic resection. Using the McCarthy resectoscope, I have removed pedunculated growths at a single operation in twenty-five cases, with gratifying results. The operation is applicable to pedunculated tumors as large as 5 cm. in diameter, or, roughly, the size of a golf ball. The method is vastly superior to repeated fulguration and in suitable cases is to be preferred to cystostomy, for I am sure the tumor can be removed more thoroughly with cystoscopic vision in the distended bladder than with the unaided eye in the opened collapsed bladder, and there is less chance of overlooking small, secondary growths in the bladder and prostatic urethra. In suitable cases it is an injustice to the patient to subject him to suprapubic cystostomy. The results of prostatic resection exemplify the widespread favorable results achieved in the past five years by those who have adopted this method and stuck to it. The large series of cases being amassed collectively indicates that (1) more patients are accepting operation because of the increased safety and (2) more are accepting operation earlier. The increased safety is reflected in the low mortality statistics that have been reported.

DR. LOUIS M. ORR JR., Orlando, Fla.: Divergent views on the subject of transurethral resection prompted an attempt to evaluate the procedure by questioning several members of the American Urological Association. One hundred and forty-six questionnaires were sent out. Sixty-eight were answered. Five recipients declined to answer. Additional questionnaires from Dr. Warren Hewins increased the total number to seventy-three. The seventy-three surgeons performed 13,104 prostatic resections and 5,062 prostatectomies during the same period. These totals show that resections are almost three times greater

in number than prostatectomies. There were also 214 operations on the bladder neck performed with the Young punch or similar "punch" instruments. The number of deaths from resection was reported to be 370, or 2.8 per cent, from prostatectomies 195, or 3.8 per cent. Primary hemorrhages accompanying resection, which necessitated opening the bladder, numbered 107. Secondary hemorrhages requiring fulguration, 164; transfusion, 116; both, fifty-four. Six hundred and forty-eight severe infections were reported associated with resection, or 4.9 per cent of all cases. Forty surgeons reserve the procedure for small glands. Thirty-two employ it in all types of hypertrophy. Four hundred and eighty-eight secondary resections were necessary because of insufficient removal of tissue at the first operation. No instance of regrowth of tissue was mentioned as a cause for the second resection. One hundred and five patients were reported who had troublesome incontinence, both temporary and permanent. Subsequent prostatectomies were performed on 172 patients who had previously had resection. This figure would probably run considerably higher if all cases of resection could be accurately followed. In most instances the men performing the largest number of resections were having the best results and recommended the operation for practically all types of prostatic obstruction. Those performing fewer resections were more cautious in their choice of operation. The majority recommended that the procedure be used in only the carefully selected cases and be limited to the smaller atrophic glands, median bars and as a palliative relief in cases of malignancy. Three men reported that they did not see any place for resection. Two asserted that the operation was based on unsound surgical principles but occasionally gave excellent results. Sound principles underly prostatic resection.

DR. A. G. FLEISCHMAN, Des Moines, Iowa: The question resolves itself into one of morbidity and what constitutes an ideal result. In some of the patients on whom more than one resection was performed, I found that there still persisted a definite amount of residual urine and infection. My own results with transurethral resection have not been as good as when I was doing a clean-cut, radical suprapubic prostatectomy. Whence do all these prostates come? There seems to be an unusual deluge of them. Probably they are being seen in an earlier stage. I recall that in a year and a half spent in one of the largest clinics in this country, under supervision of a man recognized as one of the peers in American urology, it was considered a pretty good ratio when the prostatectomies numbered from 200 to 250 a year. Some types of cases yield to ordinary massage and to noninstrumental procedures. I feel also that, besides the question of the number of prostates and the economic phase of this procedure, quality should be mentioned. Let us follow the suggestions expressed by our chairman today and train ourselves in all definite recognized methods and not develop our procedures along one track.

DR. JOHN F. PATTON, St. Louis: It may be said of transurethral surgery that it is the creator of modern urology, and as such it deserves to be preserved. The greatest strides in urology during the past decade have been made along this line, an ever increasing application of transurethral procedures for the treatment of diseases of the posterior urethra, prostate, bladder and even the ureter and kidney. The necessity for major surgery has been materially decreased and the mortality rate reduced to a marked degree. Transurethral removal of the prostate is now an accepted surgical procedure. The extent to which it is applied by any one operator is entirely an individual matter. The percentage of application in some hands is as low as 20, while in other clinics it is applied in as high as 100 per cent. If the prostate is large and the patient a good surgical risk, the gland should be enucleated. Dr. Caulk applies the cautery punch in almost 85 per cent of all obstructions; I am somewhat more conservative. Since the efficacy of this type of surgery has been proved, the operator is more concerned now with the development of its technic and the improvement of the method to the end result of lessening the complications and further reducing the mortality. In 1933, from an experimental and clinical study, Dr. Caulk and I called to the attention of the profession the deleterious effects and the hazards that may be encountered from the application of the high frequency current in prostatic resections. It is

astounding to learn that 3,000 such instruments have been sold to the profession. Certainly many of these are in incompetent hands, and the untoward complications that have resulted undoubtedly explain the unfavorable reaction which has been created in the minds of certain of the general profession toward transurethral surgery as a whole. Of the various methods employed the cautery punch and the instrument used by Dr. Thompson at the Mayo Clinic are by far the safer instruments in the hands of most men. In Dr. Caulk's series of more than 1,300 cases the mortality rate remains below 1 per cent. Hemorrhage has ceased to be a troublesome factor and sepsis is almost negligible. I have followed these cases post-operatively for the past eight years and have encountered none of the serious complications, such as extreme sepsis or rectourethral fistulas, which have been reported following the use of the high frequency current. I would like to call attention to one complication which has given trouble on several occasions, and that is a stricture at the meatus, undoubtedly due to the large catheter. At the present time, we are replacing it with a smaller one after twenty-four hours, and I believe this will be eliminated.

DR. OTTO J. WILHELM, St. Louis: I cannot present the gratifying mortality rate that has been presented here. I have gathered statistics from our work at the county hospital and from private work. It is interesting to note that there is a difference in the statistics from private and clinical work. The series include 183 private cases and 156 cases from the county hospital files, a total of 339 cases. The youngest patients were twin brothers, aged 24, who had congenital bars at the bladder neck. The oldest patient was 96; he also had a resection and left the hospital in good condition. A point of interest is that the mortality rate is definitely higher in the clinical patient, which can be explained by the extreme state of malnutrition found in these patients previous to operation. Hemorrhage still exists regardless of the type of instrument used, as the biggest bugbear in transurethral operations. And next in importance is pulmonary edema. I have come to the conclusion that pulmonary edema is an evidence of too much surgery done at one time. I mean by this that the operator gets too enthusiastic, works too long on one patient and does too much at one time, rather than doing part at one time and then resuming his work at another sitting. Quite a number of repeat operations have been done over a two and a four year period. More patients return after an interval of four years. Whether the operator is at fault here or whether this is a natural incidence, I cannot say. The question that presents itself here is: Does the operator remove sufficient tissue primarily or is this a regrowth of adenomatous tissue as occurs in poorly dissected tonsils? The severest hemorrhage and the largest vessels occur outside the 4 to 8 o'clock area on the sphincter margin. This bleeding is often so profuse that it is impossible, even with constant irrigation, to detect the bleeding points and coagulate them. In severe hemorrhage, cystotomy and packing is the only recourse.

DR. HERMON C. BUMPUS JR., Pasadena, Calif.: Three salient points have remained in my mind. First, the applicability of this procedure is proving far greater than former methods of treatment. The decreased risk has resulted not alone in many patients being treated earlier, before irreparable anatomic and physiologic changes have occurred, but many successful resections are being done in which such changes have progressed to such a point that the patients would have formerly been considered in much too poor physical condition to undergo any surgical procedure. This greater applicability is strikingly demonstrated by the series of 675 cases from the Mayo Clinic in one year reported by Dr. Thompson. Formerly not more than one third of that number of patients were considered suitable subjects for prostatectomy in that institution in any one year. The fact that in 46 per cent of these it was necessary to remove less than 10 Gm. of tissue to relieve the obstruction indicates that many are seeking relief earlier, before deformed bladders and impaired renal function have developed. That thirty-eight patients over 80 years of age in this series underwent resection without a death is certainly impressive evidence of the larger number of increased surgical risks that have been able to benefit from this procedure when employed by the experienced. Secondly, it has been demonstrated that

in the past too great importance has been placed on the pre-operative preparation of these patients. Protracted drainage is of inestimable value in the presence of impaired renal function or in the reduction of excessive infection. In the past it has been used too frequently when not required, with the result that the patients have been made poorer rather than better surgical risks. Last year I did 84 per cent of resections without such preparation and am interested to find that in Dr. Thompson's series 65 per cent were operated on without preparation. The excellent results he obtained in the 35 per cent receiving preoperative preparation attests to the keen discrimination with which it was applied. Thirdly, with each discussion of the subject it becomes more apparent that transurethral resection is a highly technical procedure, to be mastered only where a large number of cases are done, as Dr. Orr's figures illustrate. Unless one has such an opportunity to master the technic, one will derive better results by employing the older and simpler methods of treatment, leaving to the experienced this more technical and difficult procedure with its greater degree of applicability and lessened risk.

DR. GERSHOM J. THOMPSON, Rochester, Minn.: I agree that so-called prophylactic prostatic resection should be avoided. I do not believe in operating on young men. The older man is the one who has been benefited by the development of prostatic resection. Dr. Kretschmer has wisely called attention to the lack of reaction from the secondary operation; this is a point that deserves emphasis, for it strengthens my opinion that the primary resection should not extend beyond a period of forty-five minutes. I am sure much less surgical shock and mortality will result in any group of patients if, in difficult cases, the operation is done in two stages rather than in a single stage that is quite prolonged.

## THE TREATMENT OF PERIPHERAL OBLITERATIVE ARTERIAL DISEASES

BY THE USE OF INTERMITTENT VENOUS OCCLUSION:  
A REPORT OF THE RESULTS IN  
TWENTY-NINE CASES

WILLIAM S. COLLENS, M.D.  
AND  
NATHAN D. WILENSKY, M.D.  
BROOKLYN

The principle of intermittent venous occlusion and its application to the treatment of organic obliterative vascular disease have recently been reported by us.<sup>1</sup> Briefly, this procedure consists of the application to the proximal portion of an extremity of a pneumatic cuff, which is inflated to a pressure approximating the diastolic level of arterial pressure. This results in the creation of venous obstruction and when the pressure is released a state of reactive hyperemia develops. The apparatus which we have devised for this procedure is designed to create alternating periods of venous congestion and release of this congestion.<sup>2</sup>

Lewis and Grant<sup>3</sup> have demonstrated that there occurs, during the release of venous congestion, an increase in arterial flow of as much as 600 per cent, depending on the degree and duration of application of venous congestion. They showed that this increase in arterial flow is the result of an active vasodilatation,

which occurs in the arterioles. Although they found that the maximal increase in flow could be obtained by applying 90 mm. of pressure for fifteen minutes, we found that the use of this procedure in disease states functioned optimally at from 60 to 80 mm. of mercury pressure for alternating periods of two minutes.

We should like at this point to state that our method of treatment is not to be confused with alternating

Fig. 1.—Application of intermittent venous occlusion to proximal portion of extremity

suction and pressure. Whereas suction and pressure is employed by affecting the environmental pressure of an entire extremity by means of a boot, our procedure is based on the principle of reactive hyperemia obtained by the application of a pneumatic cuff about the proximal portion of the extremity (fig. 1) and does not at all influence the environmental pressure around the extremity.

We have applied this method of treatment to twenty-nine patients suffering from peripheral arterial disease. The types and distribution of these cases are seen in table 1. These cases were unselected and were used for our studies regardless of the type or severity of peripheral vascular obstruction. No other method of treatment was employed in any of these cases other than that of intermittent venous occlusion. Of course, patients suffering from ulcer or gangrene were put to bed; otherwise they were treated as ambulatory cases.

THROMBO-ANGIITIS OBLITERANS

Five patients suffering from this disease came under our observation since the application of this method of treatment. The most outstanding results in this series were the complete and rapid relief of pain and the ability of the ulcers to heal.

One patient (fig. 2) had been suffering from thrombo-angiitis obliterans for twelve years. Ten years before,

his right leg was amputated in the midhigh region. Eight years before, he developed an ulcer on the dorsum of his left large toe which rapidly spread to cover the entire dorsum of his foot. He had received 300 cc. of 5 per cent salt solution intravenously three times a week for seven years without relief of pain or any influence on the state of his ulcer. He had been an in-bed patient in Montefiore Hospital for fifteen months, during which time he received, besides intravenous hypertonic saline solution, typhoid vaccine intravenously and local exposures of the ulcer to ultraviolet rays. One year before, in order to relieve his pain, he had a section performed on all the peripheral nerves, including the anterior and posterior tibials, peroneal and musculocutaneous. Although his pain immediately dis-

appeared, all his toes became gangrenous within two weeks and spontaneously amputated subsequently. The size of the ulcer did not change. At the end of a year the pain returned. He left the Montefiore Hospital and finally entered the Israel Zion Hospital, begging for an amputation. The patient was observed for three days during which time it was necessary to administer enormous doses of sedatives and narcotics. Intermittent

Fig. 2.—Ulcer in case of thrombo-angiitis obliterans treated for eight years by almost every known method, including intravenous hypertonic saline solution, bed care, baking, diathermy, ultraviolet ray exposure, typhoid vaccine and skin grafts: A, before and B eight weeks after intermittent venous occlusion; completely healed.

venous occlusion was then applied. At the end of twelve hours of treatment, the patient began to notice some relief of pain. Within five days he was able to sleep without the use of any narcotic or sedative. In eight weeks the ulcer completely healed (fig. 2).

Relief of pain in less than twenty-four hours has been noticed in all the other cases of thrombo-angiitis

obliterans. Granulation tissue appeared in the ulcers, which showed evidence of ability to heal far better than with any other method with which we had previously had any experience. A summary of the cases is seen in table 5. Detailed summaries of results regarding pain relief appear in table 2, healing of ulcers in table 3 and increase in walking ability in table 4.

Fig. 3.—Improvement in walking ability in case of arteriosclerosis with intermittent claudication. A, ceased walking because of dyspnea.

#### ARTERIOSCLEROSIS OBLITERANS

The degenerative forms of arterial disease recognized as arteriosclerosis are much more common than thrombo-angiitis obliterans. Arterial obstruction occurring in later life is manifested in the nondiabetic patient by disturbance in vascular capacity, with resultant intermittent claudication. The same phenomenon in the diabetic patient is curiously followed by trophic changes in the skin, rapid and progressive infection, and ul-

Fig. 4.—Improvement in walking ability in case of arteriosclerosis with intermittent claudication.

mately gangrene. This is borne out by our own records (table 1). Although the diabetic suffered in a slightly larger proportion than the nondiabetic, the incidence of gangrene or ulcer was in the proportion of twelve to one.

This serious problem in later life thus becomes concerned with the relief of claudication in the nondiabetic, while it becomes one of restoring tissues and aiding

healing in the diabetic. It is common knowledge that the last group of cases represent a class for which the physician has been able to do the least good and has been solved in the majority of cases by performing mid thigh amputations. As a group, however, they present vessels which are hard, unwieldy, frequently calcified, with little collateral flow, and, when complicated by a diabetic state, become markedly susceptible to rapid, spreading infection with profound death of tissue.

All previous methods of treatment, whether by physical therapy, suction and pressure, tissue extract, hypertonic saline solution or typhoid vaccine have been admitted to fail notoriously in this group. Our experience with intermittent venous occlusion has included twenty-three cases in this class of disease, thirteen of which were diabetic and ten nondiabetic (table 1). In the summary of our results (table 5) one can observe a rather encouraging picture. The details of effect on the relief of rest pain is seen in table 2. Of twenty-three cases, including all types of arteriosclerosis obliterans, with or without gangrene, complete relief of

Fig. 5.—Diabetic gangrene of four months' duration: A, foot edematous, lesion foul, lymphangitic streaks present, febrile, oscillometric readings absent up to knee; B, after four months' treatment—spontaneous amputation, healthy granulation tissue, and adequate epithelization.

pain was obtained in seventeen, partial relief in five and no relief in two. It is interesting to note that, when pain relief occurred, it was apparent in from two to forty-eight hours. We believe that this presents a better result than has been obtained with any other previous method.

With regard to the question of gangrene, we must confess a number of failures. We believe that frank gangrene in two cases of diabetes was made definitely worse by our treatment and hastened amputation. We were, however, encouraged to find four cases that healed and five others that were healing at the time of this writing. These are cases in which there is profound arterial obstruction that we feel would have become progressively worse under our previous methods of approach.

One of the most striking results was in the group of arteriosclerosis with intermittent claudication. The marked increase in vascular capacity that enabled these patients uniformly to improve their walking ability markedly is seen in figures 3 and 4.

## COMMENT

Our experience with the use of intermittent venous occlusion extends over a period of a year and a half. We have observed that those patients suffering from organic arterial occlusion without ulcer or gangrene derived the greatest degree of relief and produced the best results when the pressure was applied at levels of from 80 to 90 mm. of mercury for as much as twelve hours a day. After two weeks of continuous treatment of this character, they would subsequently return for treatment for periods of two hours three to four times a week.

We have found that it is necessary to continue these interval treatments in cases of arteriosclerosis obliterans. The patients themselves voluntarily return for these treatments, for they themselves have found that if treatment is interrupted for two weeks their symptoms have a tendency to return. In figure 4 one will observe a reduction in vascular capacity after cessation of treatment for one month with the subsequent improvement on the resumption of treatment.

TABLE 4.—Summary of Results of Treatment with Intermittent Venous Occlusion; Effect on Walking Capacity and Intermittent Claudication

	Before Treatment (Feet)	After Treatment (Feet)	Duration of Treatment
Thrombo-anglitis obliterans.....	100	1,000	4 weeks
Arteriosclerosis obliterans (nondiabetic)			
Patient 1.....	400	1,250	4 weeks
2.....	250	920	2 weeks
3.....	510	940	3 weeks
4.....	400	820	2 weeks
Arteriosclerosis obliterans (diabetic).....	600	2,350	3 weeks

The walking rate was 11 paces in each five seconds.

In the cases showing evidence of ulcer or gangrene we have been able to obtain the greatest amount of relief by maintaining a pressure of from 40 to 50 mm. of mercury for periods of one hour alternating with one hour of rest during the waking hours. In some of these cases we found that if treatment was given continuously there developed a slight edema of the foot, which would disappear after the discontinuance of treatment for a day.

We have in some cases observed after two to three weeks of treatment that there occurred visible traces of an arterial pulse in the oscillometer which had been previously totally absent.

We have found the venous filling test, which we described recently,<sup>4</sup> an excellent criterion for determining quantitatively any change in vascular capacity. The test is performed by elevating the feet above the level of the head and moving the toes until the foot is blanched and the veins are collapsed. On placing the feet in the dependent position, the time is noted that it takes the veins on the dorsum of the foot to fill with blood. Since the lunar valves in the veins prevent a reflux of blood into the peripheral circulation, whatever blood enters the veins of the dorsum of the foot must obviously come from the arteries and through the capillaries. We have found that the normal venous filling time is from eight to ten seconds. In pathologic states

the delay in venous filling is directly proportional to the degree of vascular obstruction. We have seen in some cases a marked degree of improvement in the venous filling time after the institution of our treatment.

In experimental studies of the effect of intermittent venous occlusion in normal extremities we have seen a rise in skin temperature of as much as 3 degrees F. after one hour of treatment. In one case of arterio-sclerosis obliterans the temperature rose as much as 4 degrees F.

Of all the ulcers that have healed in our series, not one has subsequently broken down.

## CONCLUSIONS

1. A new method of treating peripheral obliterative arterial disease by the use of intermittent venous occlusion has been developed.

2. In twenty-nine unselected cases this method of treatment was capable of relieving pain, healing ulcers and increasing walking capacity.

3. Our experience shows that the physiologic observations of Lewis and Grant in the normal are basically sound in their application to the treatment of peripheral vascular disease.

## Clinical Notes, Suggestions and New Instruments

### A CASE OF INFANTILE ADIPOSIS TREATED WITH THYROID

M. MORRIS PINCKNEY, M.D., AND ROLLAND J. MAIN, PH.D.  
RICHMOND, VA.

S. E., a girl, weighed 3.9 Kg. at birth after an uncomplicated delivery and appeared normal. The child was breast fed for several months after birth and received orange juice daily but no added source of vitamin D. Teething began at the age of 6 months. The mother noticed that, starting at the age of 7 months, the infant gained weight very rapidly, until it was brought to the Pediatrics Clinic, Jan. 17, 1933, at the age of 13 months with the complaint of extreme obesity. The infant had experienced no illness up to that time, and its behavior had appeared normal to the parents. There was no history of tuberculosis, syphilis, diabetes or thyroid or pituitary dysfunctions in the family. A brother, born a year later, and an older sister, aged 11 years, were normal.

Beyond the marked adiposity (the weight was 15 Kg. as compared to the normal average of 9.1 Kg., fig. 1A), the only abnormalities reported were a reddened skin, a thrush infection and carious teeth. A specimen of the urine was negative for sugar, and a roentgenogram of the skull revealed no abnormalities. Whole dried pituitary (65 mg. twice daily) and fortified halibut liver oil were administered for two months, when the pituitary was discontinued and thyroid (30 mg. three times daily) given for three weeks (fig. 1B). The weight steadily increased throughout this treatment until the patient weighed 17.3 Kg. May 29 (fig. 1C), when whole pituitary (65 mg. three times daily) was again given for a period of several months. Calcium lactate was likewise prescribed because of her very carious teeth. Vitamin D was not given constantly because the patient refused cod liver oil, and it was impossible at that time to obtain a constant supply of the more concentrated preparations because of the expense.

October 12 the patient was transferred to the Endocrine Clinic. At this time, at the age of 22 months, she weighed 17.5 Kg. (fig. 1D) and presented an extremely grotesque

none in the axillae or about the genitalia. The skin was dry and thick, and the cheeks were very red. A small umbilical hernia was present.

The appetite was poor, the total food intake being rather below average. Constipation, but no polydipsia or polyuria, was present. Roentgenograms revealed an apparent enlargement of the thymus and a markedly deficient ossification of the bones of the wrist and foot.

Her physical measurements, which indicate that there was a marked deficiency of stature, are given in table 1.

These observations led us to postulate a pluriglandular disturbance, for such extreme adiposity is not typical of hypothyroidism alone but suggests the obesity resulting from injuries to the pituitary or hypothalamus. A dysfunction of the adrenal cortex was considered but dismissed as improbable because of the lack of development of the secondary sex characteristics, such as pubic hair.

However, because of the paucity of evidence in the literature on the efficacy of desiccated pituitary by mouth, and because of the previous failure of this substance to reduce the patient's weight (fig. 1A-B,C-D), we determined to use desiccated thyroid, which had previously been administered for a period

TABLE 1.—Physical Measurements at 22 Months

	Patient's	Normal
Vertex to symphysis.....	40.6 cm.	49.5 cm.
Symphysis to sole.....	31.8 cm.	33.5 cm.
Total length.....	72.4 cm.	83.3 cm.
Circumference of head.....	45.0 cm.	48.0 cm.
Chest.....	60.0 cm.	48.0 cm.
Abdomen.....	65.0 cm.	
Hips.....	63.0 cm.	

of but three weeks (fig. 1B). Dried thyroid (30 mg. four times daily) was therefore prescribed, as well as calcium lactate (0.3 Gm. three times daily) and halibut liver oil for the deficient calcification. We did not consider that the "apparently enlarged" thymus need be considered, since it was not producing any mechanical obstruction.

Two weeks later the weight had increased to 17.7 Kg., but the mother reported that the child's mental alertness had greatly increased and that she was attempting to talk for the first time. Because of the slight gain in weight, the thyroid dosage was increased to 30 mg. five times daily. Under this regimen the weight fell rapidly to 16.5 Kg. December 7 (fig. 1D-E). The child no longer cried continuously when brought to the clinic as formerly and seemed much more alert. Its appetite was still poor and considerable constipation remained. The calcium and fish liver oil were continued.

Unfortunately an attack of bronchopneumonia occurred Jan. 7, 1934 (fig. 1E), requiring two weeks of hospitalization. Thyroid therapy was discontinued during this period but was resumed thereafter. Because of the inclement weather the child was seen only at home, where she could not be weighed, until she was again brought to the clinic, March 15, when she weighed 15.2 Kg. (fig. 1F). Her condition was quite satisfactory, although she was still obese. The thyroid was continued (30 mg. four times daily) with calcium and fish liver oil.

The weight now remained stationary at about 15 Kg. May 10 (fig. 1G) she showed marked improvement in appearance, the bizarre facial distortion, as well as the redness of the face, having disappeared.

An attempt was made to substitute thyroxine (0.8 mg. once daily) for the desiccated thyroid, but the child became irritable and nauseated within a few days, so that thyroid was resumed (30 mg. five times daily).

December 13 (fig. 1H) the weight had diminished to 12.9 Kg. Roentgenograms of the hands and feet indicated that the bone age was now normal, but the general transparency of the bones suggested a deficiency in calcium.

Thyroid therapy was discontinued in April 1935 (fig. 1I) because of the failure of the parents to bring the child to the clinic until June 27 (fig. 1J), at which time the weight was 13 Kg. (normal 14.2 Kg.) and the height 80 cm. (normal 95 cm.) at the age of 3½ years, indicating that a marked deficiency of stature was responsible for the child being now underweight. The mentality and behavior appeared normal. Since the teeth were in such poor condition, calcium and vitamin D were continued. Thyroid was not prescribed, since

Fig. 1.—Dots indicate the stripped weight of the patient in pounds plotted to age. Solid line shows growth of the average female child (after U. S. Children's Bureau). The weight of our patient falls below normal at the end because of small stature. Hatched horizontal blocks indicate administration of whole pituitary by mouth and solid horizontal blocks indicate thyroid therapy. A, Jan. 17, 1933: weight, 15 Kg.; aged 13 months; patient entered clinic and was given whole pituitary by mouth. B, March 21: weight 16.8 Kg.; pituitary discontinued and thyroid given for three weeks. C, May 29: weight 17.3 Kg.; figure 2 was made; whole pituitary resumed. D, October 12: weight 17.5 Kg.; pituitary therapy discontinued and thyroid administered. E, Jan. 7, 1934: attack of pneumonia; thyroid discontinued for three weeks. F, March 15: weight 15.2 Kg. G, May 10: weight 15 Kg. H, December 13: weight 12.9 Kg.; thyroid reduced to 30 mg. three times daily. I, April 1935: thyroid discontinued by parents. J, June 27: weight 13 Kg.; no thyroid. K, August 29: weight 12.7 Kg.; figure 4 was made; thyroid (30 mg. three times daily) administered for five weeks and again discontinued by parents. L, March 12, 1936: weight 13.4 Kg.; intelligence tests made; thyroid (30 mg. two times daily) again prescribed.

appearance because of her distorted face and marked obesity (fig. 2). The facial deformation by fat was such as to prevent the patient from closing her mouth, and the upper anterior teeth were almost completely destroyed by caries. There was a noticeable hirsutism of the face, back, arms and legs but

From the Endocrine Clinic, Department of Pediatrics, and the Department of Physiology, Medical College of Virginia, Richmond, Va.

We are indebted to the School of Dentistry, for cooperation; also to E. R. Davis & Co. for thyroid.

the parents were not able to bring the child to the clinic regularly. The texture of the skin was quite normal and the hirsutism had disappeared.

The patient was next seen August 29, when figure 3 was made (fig. 1K). Thyroid (30 mg. two times daily) was again prescribed for a month because the deficient height, protruding abdomen and umbilical hernia were suggestive of cretinism. Unfortunately the parents were so well satisfied with the child's improvement that they did not trouble to return her to the clinic until March 12, 1936 (fig. 1L). Her physical measurements at this time, at the age of 4 years and 3 months, are given in table 2.

TABLE 2.—Physical Measurements at the Age of 4 Years and 3 Months

	Patient's	Normal
Vertex to symphysis.....	49 cm.	56 cm.
Symphysis to sole.....	37 cm.	44 cm.
Total.....	86 cm.	100 cm.
Weight.....	13.4 Kg.	15.5 Kg.

This indicated that the child was growing slowly, although she was still 14 cm. under normal height. Her dentition was normal except for failure of eruption of the upper second deciduous molars on both sides. The teeth were carious and deeply pigmented.

She appeared alert and cooperative but did not always voluntarily control her urination, although the latter may well have been due to poor training. The mother reported that the child slept normally and did not suffer from constipation.

Application of the Stanford-Binet and Gesell tests revealed that there was a definite retardation in mental development, with both mentality and behavior falling between the 2 and 3 year levels, although the actual age was 4 years and 3 months.

Because both physical and mental stigmas strongly suggested cretinism, thyroid medication was begun again (30 mg. two times daily) with the idea that it will probably need to be administered for a period of years. The fish liver oil is also being continued.

#### COMMENT

We do not believe that adiposity in this case could have been due to exogenous causes, for the appetite had always been poor and the child had been breast fed for only a few months.

We consider that the condition was caused

Fig. 2.—Appearance of the patient May 29, 1933, at the age of 1 year and 5 months, weighing 17.3 Kg., before continuous thyroid therapy was instituted. The distortion of the face by fat made it impossible for the patient to close her mouth and narrowed the palpebral fissures. The ruddy cheeks are noticeable.

by a pluriglandular dysfunction, probably involving at least the pituitary and thyroid glands. The thyroid itself could not alone be responsible, for even cretins do not show such marked obesity, nor did the appearance of the patient at first suggest cretinism. However, the thick dry skin and delayed ossification may well have been due to a thyroid deficiency, especially since they were so markedly alleviated by treatment with thyroid. Obesity due to pituitary dysfunction or hypothalamic

lesions is well known, however, and strongly suggests that some such syndrome was concerned in our case.

We have no explanation for the sudden development of this condition at the age of 7 months, since there was no record of cranial injury at any time nor of any previous illness. Development of a brain tumor seemed unlikely because of the absence of gross signs of increased intracranial pressure, such as headaches, vomiting and convulsions.

Photographs of other obese infants usually do not show the peculiar distortion of the face by fat as in our case. However, a case of thymic hyperplasia and suspected adrenal cortex dysfunction reported by Engelbach<sup>1</sup> resembled our case to some extent, although that patient at the age of 4 years had premature development of pubic hair not found in ours. Guthrie and Emery<sup>2</sup> also report a somewhat similar case of "precocious obesity" but with hirsutism, which presented neither grossly abnormal adrenals nor brain tumor at necropsy. Had our case remained untreated, precocious secondary sex characteristics might have developed later.

The loss in weight and general improvement of the patient under continuous thyroid therapy was gratifying although surprising in view of the undoubted pluriglandular syndrome present. The results serve to corroborate our primary diagnosis of a pituitary-thyroid dysfunction, for it is not likely that a tumor of the adrenal cortex would have been benefited by the treatment used.

The disturbance of calcium metabolism, as indicated by the very carious teeth and relatively transparent bones, in spite of fairly adequate calcium and vitamin D therapy, may indicate an overactivity of the parathyroid glands. The short stature, 14 cm. below normal at the age of 4 years, may be due either to deficient thyroid secretion or to pituitary growth hormone.

Our patient's obesity is exceeded by many reported cases. Hempleman<sup>3</sup> records one child weighing 42 pounds (19 Kg.) at 6 months, another 34 pounds (15.4 Kg.) at 7 months, and a third 46 pounds (21 Kg.) at 16 months. Talbot's<sup>4</sup> patient weighed over 54 pounds (24.5 Kg.) at 2 years 9 months and, like ours, showed no appreciable response to desiccated pituitary, but apparently thyroid was not given and it continued to gain weight. It is noteworthy that dried whole pituitary by mouth (fig. 1, A-B, C-D) also failed to diminish the weight of our patient.

#### SUMMARY

An infant had extreme obesity developing at the age of 7 months, with rapid increase in weight up to 17.5 Kg. at the age of 1 year and 10 months. Continued thyroid therapy produced a marked loss of weight and noticeable improvement in mentality and behavior, as compared to apparent failure of desiccated whole pituitary therapy.

116 East Franklin Street.

A SPLINT TO MAINTAIN ROTATION IN THE  
LOWER EXTREMITY

A. M. RECHTMAN, M.D., PHILADELPHIA

A splint that I first saw used by my late colleague and friend Dr. William Jackson Merrill, during the 1932 poliomyelitis epidemic in Philadelphia, is here described. It serves to aid in maintaining the lower extremities of bed patients in

Fig. 1.—Front view of splint.

any desired degree of rotation. A circular plaster is applied from the toes to the knee or higher. A board or two thicknesses of basswood, about 3 inches wide and 10 inches long, is fastened with another plaster bandage to the under surface of the plaster, proximal to the heel. The board should be in the same plane as the bed when the patient is recumbent. The plaster may be bivalved and the lower portion used as a removable splint.

If it is desired to maintain the extremity in an attitude of outward rotation, the longer arm of the board should be fitted to extend well to the inner side of the plaster and vice versa.

Fig. 2.—Side view of splint.

This will aid in better balancing the extremity and maintaining the correction. The board may be centered beneath the plaster if the neutral position is desired.

The illustrations show the splint applied to the foot and leg of a boy, aged 3½ years, who had a congenital deformity of the hip with soft tissue contractions holding the extremity in an attitude of 90 degrees of external rotation. The deformity was corrected at operation by a subperiosteal stripping of the soft tissues and capsule from the trochanters and femoral neck through a posterior incision (Burman procedure). A plaster

spica was worn for four weeks. When the plaster was removed the extremity was tender and painful on motion. The splint here described was applied and it efficiently maintained the extremity in an attitude of 15 degrees of internal rotation until the soreness disappeared and passive manipulation and active exercise could be instituted without causing pain.

A few indications for the use of the splint are: 1. To maintain the desired degree of rotation in the lower extremities during the period of bed treatment for poliomyelitis. 2. As a postoperative dressing for the lower extremities of patients who have had poliomyelitis. 3. In the treatment of patients with congenital and acquired deformities and in conjunction with many fracture dressings of the lower extremities. In short, it may be incorporated in any plaster dressing of the lower extremity when it is desired to hold the part in a particular degree of rotation.

The advantages of this splint are that a lower extremity may be maintained in any degree of rotation without application of

Fig. 3.—Top view of splint.

a spica dressing; the pelvis, hip and thigh may be exposed for treatment with physical therapy and wounds may be more easily dressed. The use of uncomfortable and inefficient sand bags may be eliminated.

1715 Pine Street.

**Council on Physical Therapy**

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT. HOWARD A. CARTER, Secretary.

**BURDICK TRIPLEX UNIT, SWD-10,  
ACCEPTABLE**

Manufacturer: The Burdick Corporation, Milton, Wis.

This apparatus is a short wave diathermy machine designed for medical and surgical diathermy. Medical diathermy may be applied either by electric field or by electromagnetic field.

The short wave 15 meter circuit is designed for the application of medical diathermy to localized areas, by means of electric field cuffs and pads.

The 25 meter circuit is designed to produce therapeutic heat in the body tissues by electromagnetic induction. Application of the current is accomplished by means of a cable and may be used for heating in localized areas and for the production of therapeutic fever.

The 70 meter long wave circuit is designed for use in electro-surgery—cutting and coagulation—and for official diathermy application with metal electrodes in contact.

The circuit is the well known push-pull type radiofrequency oscillator, modified in design so that the tubes can be switched to the different type circuits. The unit uses two oscillator tubes. The power transformer is furnished with two balanced secondary coils and five line voltage taps. A separate transformer is provided with the filaments. Figure 2 is a diagram of the circuit.

When this machine is operated under full load it draws not more than 1,000 watts from the line. Since no reliable method has been proposed to measure the output of energy available to the patient, this value is not given.

From the orthopedic service of the author at the Jewish Hospital in Philadelphia, the Atlantic City Hospital and the Coatesville Hospital.

The accessories furnished with the unit are one 12 foot inductance cable applicator, two 7 by 9 electric field pads, one 3 by 7 electric field pad, one 4 by 13½ cuff and one 4 by 16 cuff.

The manufacturer submitted evidence substantiating the heating claims that are made for this unit.

Fig. 1.—Burdick Triplex Unit.

Three vigorous adult male medical students ranging from 150 to 180 pounds were used for the experiments. Two trocars placed in hard rubber cannulas were inserted into the thigh and straight down into the depth of the muscular tissue until the instrument was at an approximate depth of 2 inches or until the femur was encountered. The second was introduced as nearly parallel to the skin as possible and subcutaneously at an approximate depth of one-eighth inch. The trocars were removed and the rubber cannulas left in situ. Temperature measurements were then taken by means of thermocouples of the hypodermic needle type and introduced through the cannulas. The constant junction was immersed in ice enclosed in a quart vacuum bottle. The electromotive force due to the difference in temperature of the junctions was read in millivolts from a Leeds-Northrup portable potentiometer. The thermocouples were calibrated in degrees Fahrenheit against a Bureau of Standards certified thermometer. Initial temperatures were taken and then each subject was submitted to a twenty minute application of maximum current intensity consistent with skin comfort. At the end of this period, temperatures were again recorded until the temperature began to drop. The highest temperature attained was recorded as final temperature, in each instance. Oral temperatures were also recorded.

The technic of application included: First, 15 meters. Double cuff technic. Two cuffs, 4 by 16 inches, were wrapped around the thigh equidistant from the cannula, approximately 9 to 11 inches center to center, and with three-eighths inch felt spacing.

Second, 25 meters. Coil technic. Four turns of the cable were wound around the thigh with six layers of bath towels for spacing, and each coil approximately 2 inches from its neighbor.

In the accompanying table, each reading is the average of six observations.

Fig. 2.—Diagram of circuit

The technic of application included: First, 15 meters. Double cuff technic. Two cuffs, 4 by 16 inches, were wrapped around the thigh equidistant from the cannula, approximately 9 to 11 inches center to center, and with three-eighths inch felt spacing.

Second, 25 meters. Coil technic. Four turns of the cable were wound around the thigh with six layers of bath towels for spacing, and each coil approximately 2 inches from its neighbor.

In the accompanying table, each reading is the average of six observations.

#### Results of Tests

Tech- nic	Wave- length	Quadriceps Muscle Deep Temperature		Subcutaneous Superficial Temp.		Oral Temperature	
		Initial	Final	Initial	Final	Initial	Final
Cuff ...	15	99.05	105.18	97.36	103.40	98.95	99.30
Coil ...	25	99.63	106.60	98.03	105.23	98.80	99.55

The temperature rise of the transformer, after the machine had been operated at full load for two hours, came within the limits of safety prescribed by the Council. The shipping weight of the apparatus is about 250 pounds. Burns may be produced,

but they may be avoided by ordinary precaution. Their likelihood to occur is much less than with conventional diathermy.

This machine was installed in a clinic acceptable to the Council and operated under actual clinical conditions. It was found to give satisfactory service. In view of the favorable report, based on the performance of this unit when cuff electrodes or coil technic were used, the Council on Physical Therapy voted to include the Burdick Triplex Unit, SWD-10, in its list of accepted devices.

## Council on Pharmacy and Chemistry

### NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH, Secretary.

#### DIPHTHERIA TOXOID, ALUM PRECIPITATED (REFINED) (See New and Nonofficial Remedies, 1936, p. 392).

Hixson Laboratories, Inc., Johnstown, Ohio.

*Diphtheria Toxoid, Alum Precipitated (Refined).*—Prepared from diphtheria toxin having an L+ dose of 0.20 cc. or less and an M. L. D. value of 0.0025 cc. The toxin is treated with formaldehyde at a temperature of from 38 to 40 C. until its toxicity is so reduced that five human doses will cause no local or general symptoms of diphtheria poisoning when injected subcutaneously into guinea-pigs under observation for thirty days. The toxoid is precipitated with a solution of aluminum and potassium sulfate in such amount that the finished product shall not contain more than 20 mg. of alum per human dose. The supernatant solution is siphoned off and discarded. The precipitate is washed three times with sterile physiologic solution of sodium chloride and resuspended in sterile physiologic solution of sodium chloride so that the final volume is equal to that of the original toxoid. The finished product contains 1:10,000 merthiolate as a preservative. The immunizing value of the diphtheria toxoid-alum precipitated is determined according to the regulations of the National Institute of Health; namely, the human dose administered subcutaneously to at least four guinea-pigs weighing 500 Gm. produces at least two units of antitoxin per cubic centimeter of blood serum at the end of four weeks. Marketed in packages of one 1 cc. vial (one immunization), ten 1 cc. vials (ten immunizations) and one 10 cc. vial (ten immunizations).

#### PHENOBARBITAL SODIUM-ABBOTT (See New and Nonofficial Remedies, 1936, p. 112).

The following dosage forms have been accepted:

*Ampoules Phenobarbital Sodium (Powder)-Abbott, 0.13 Gm. (2 grains). Tablets Phenobarbital Sodium-Abbott, 0.1 Gm. (1½ grains).*

#### THROMBOPLASTIN LOCAL-SQUIBB (See New and Nonofficial Remedies, 1936, p. 220).

The following dosage form has been accepted:

*Thromboplastin Local-Squibb, Dental Package, six 4 cc. vials.*

#### HALIBUT LIVER OIL (See New and Nonofficial Remedies, 1936, p. 459).

*McKesson's Halibut Liver Oil with Vitamin D Concentrate in Neutrol Oil; Capsules, 3 minims.*—The content of each capsule is assayed to contain not less than 10,000 units (U. S. P.) of vitamin A and 945 units (U. S. P.) of vitamin D.

Manufactured by the International Vitamin Corporation, New York (McKesson & Robbins, Inc., Bridgeport, Conn., distributor). No U. S. patent.

*McKesson's Halibut Liver Oil Plain, 11 cc.*—A brand of halibut liver oil-N. N. R.

Manufactured by the International Vitamin Corporation, New York (McKesson & Robbins, Inc., Bridgeport, Conn., distributor). No U. S. patent.

*McKesson's Halibut Liver Oil Plain, Capsules, 3 minims.*—The content of each capsule is assayed to contain not less than 10,000 units (U. S. P.) of vitamin A and not less than 170 units (U. S. P.) of vitamin D.

McKesson's halibut liver oil plain is prepared by extracting the oil of fresh halibut livers. The oil is refined and assayed to have not less than the potency of halibut liver oil-N. N. R.

#### SCARLET FEVER STREPTOCOCCIC TOXIN, U. S. P. (See New and Nonofficial Remedies, 1936, p. 411).

Mulford Biological Laboratories, Sharp & Dohme, Philadelphia and Baltimore.

*Scarlet Fever Streptococcus Toxin for the Dick Test-Mulford:* Prepared by the method of Drs. Dick under U. S. Patent 1,547,369 (July 29, 1925; expires 1942) by license of the Scarlet Fever Committee Incorporated. Marketed in 1-cc. ampoules containing diluted toxin ready for immediate use sufficient for ten tests (in 0.1 cc. doses); also in packages of one 10-cc. ampule-vial containing diluted toxin ready for immediate use, sufficient for 100 tests.

## MATERNAL TRANSFERENCE OF FLUORINE

During the past six years, fluorine has assumed considerable importance as a problem in public health. The most chemically active of the halogens, the toxic properties of this element and its soluble salts have long been appreciated. However, the recent attention given to fluorine has been elicited by the demonstration that mottling of the enamel of teeth is caused by extremely small concentrations of this substance in food and water. Instead of the normally smooth, translucent surface of the tooth, the affected structures appear dull, with chalky white areas which later frequently become stained in an unsightly manner. In severe cases, actual pitting may occur. The result in any case is permanent disfigurement, for new enamel ceases to form with the eruption of the tooth. In a recent review, Dean<sup>1</sup> has indicated the wide distribution of endemic fluorosis in this country. The continued use of drinking water containing as little as one part per million of fluorine will produce mild dental changes in a small proportion of children; with six parts per million, the incidence of moderate mottling is usually 100 per cent. As fluorine exerts its deleterious effect only during the period of development of the tooth, damage can be prevented by changing the source of drinking water, a device that has proved of practical benefit, or by suitable dilution of contaminated water with other water not containing fluorine.

Although wide investigative effort has been devoted to the etiology of mottled enamel, little attention has heretofore been given to pathways of entrance of fluorine into the organism other than through the drinking water and food. That fluorine can pass the placenta and gain entrance to the fetus is shown by a recent study of Murray.<sup>2</sup> One group of pregnant female albino rats was given an adequate ration and another group received the same diet plus 0.05 per cent of sodium fluoride. Within twenty-four hours after birth

the litters were killed and ashed and the fluorine in the ash determined. Roughly five times the fluorine content of the control animals was found in those the mothers of which consumed the fluoride-containing food. The actual difference represents an amount which from other studies would seem to be harmful to the organism. In a further experiment the relative influence of contact with fluorine during gestation and the consumption of milk from mothers ingesting fluoride was determined by analyzing the bones of the young at 21 days of age. The results show that the young absorb fluorine when it is administered to the mothers both before the birth and after the birth of the litters. There is not only placental transmission of fluorine but also excretion through the milk.

Heretofore attention has been given largely to the fluorine content of drinking water consumed during the first eight years of life, the period of development of the permanent teeth. The foregoing discussion indicates that mottling of the temporary teeth may result from antepartum maternal fluorosis and that, in regions of endemic fluorosis, milk may contain biologically effective amounts of this element. The fact that, in certain parts of the world, dental fluorosis is prevalent in cattle and sheep and that fluoride is present in certain samples of rock phosphate which may be used as fertilizer for farm and garden crops indicates the many directions in which one may be exposed to fluorine even in regions where it does not occur naturally.

## BLOOD CHOLESTEROL AND ATHEROSCLEROSIS

The feeding of cholesterol to rabbits has been repeatedly shown to produce an experimental atherosclerosis characterized by the deposition of lipids in both the intima and the media of the aorta and less frequently perhaps of other blood vessels.<sup>1</sup> The exact nature of the changes involved in the production of the lesions, however, is not clearly understood. It was once thought that the vascular changes were primarily dependent on the development of a hypercholesterolemia.<sup>2</sup> If for unknown reasons the lipid content of the blood remained normal, cholesterol was not deposited in the walls of the vessels. Subsequent studies have indicated, however, that other factors are undoubtedly involved. In a recent investigation,<sup>3</sup> for example, the feeding of cholesterol to rabbits for as long as thirty-one days in amounts sufficient to cause a hypercholesterolemia failed to produce atherosclerosis. Nor did treatment with substances injurious to the vascular system, as the intravenous injection of streptococcus toxin, peptone or uric acid, the feeding of ammonium chloride, the production

of artificial fever or the induction of anaphylactic shock, increase the incidence of cholesterol lesions in the aorta. Evidently, the mechanism involved in the production of atherosclerosis in the rabbit by cholesterol feeding is not a simple one.

As a result of the earlier work on experimental atherosclerosis in this species, some investigators have placed emphasis on the importance of cholesterol as an etiologic factor in human atherosclerosis. Indeed, some believe that hypercholesterolemia is a primary etiologic factor in spontaneous atherosclerosis of man. However, a number of attempts to demonstrate such a relationship in patients have not yielded conclusive results, partly because of the extremely wide variation in serum cholesterol found in normal persons and partly because of the fact that during life the disease is recognized only after the process has advanced so far that secondary functional disturbances, which themselves alter the serum cholesterol level, vitiate the results. Obviously, it is necessary to make the comparison during the early stages of the disease when the deposits are in process of formation. However, this approach to the question is complicated by the fact that patients in the early stage of atherosclerosis are rarely seen, since symptoms which would cause them to consult a physician usually do not develop then. Also the diagnosis of the disease at that stage is exceedingly difficult. In fact, the degree of atherosclerosis can be established with certainty only by a direct examination of the vessels, a procedure necessarily limited to necropsy material.

Recently<sup>4</sup> this problem has been approached in a way that appears to be free from the objections cited. A comparison of the concentration of cholesterol in the blood serum with the lipid content of the intima of the aorta was made on necropsy material taken from persons who had died suddenly, in most instances as a result of automobile accidents. A total of 123 cases, some with varying degrees of atherosclerosis, were selected for study; no material was taken from subjects in whom pathologic processes other than atherosclerosis were found. The values obtained gave no indication whatever of a correlation between the concentration of cholesterol in the serum and the lipid content of the aorta, even in subjects with a marked degree of atherosclerosis. Indeed, the average and the variations in the amounts of cholesterol in the serum were practically identical with those usually found in normal healthy subjects. The foregoing results, both in rabbits with experimental atherosclerosis and in man with varying degrees of spontaneous atherosclerosis, clearly indicate that factors other than the concentration of cholesterol in the blood must be involved as etiologic agents in the production of the lesions characteristic of this disease.

#### EXPERIMENTAL EPIDEMIOLOGY

The study of experimental epidemics recently reported by Greenwood, Hill, Topley and Wilson<sup>1</sup> involves observations extending over some fifteen years and the use of between 100,000 and 200,000 mice. Their methods were adequately controlled and ably presented. In fact, so carefully was their technic developed that it usually proved possible to maintain herds of mice for months or years without the accidental introduction of any extraneous infection.

In one series of observations, six different epidemics of pasteurellosis were under simultaneous observation. In the long continued epidemics under these experimental conditions, no tendency for periods of high or low mortality to recur at definite seasons of the year was noted. Uncontaminated animals were introduced to many of their herds of infected mice at stated intervals. The great majority of such mice were infected shortly after entrance, so that the reacting system at any moment contained a relatively small proportion of animals presenting a virgin soil. After the first wave of disease and death that always follows the aggregation of an infected herd, the epidemics settled into a state of unstable equilibrium. With a small number of daily uninfected immigrants, the mortality curves tended to show relatively wide and relatively regular fluctuations.

The observations on ectromelia—a virus disease of mice—gave encouraging results, which accorded with the general experience that antiviral immunity is as a rule more effective than antibacterial immunity. In this disease, even under the severest conditions of prolonged exposure, a relatively high degree of protection could be attained.

The general conclusions resulting from this important study are carefully restricted to mice. The authors were careful to maintain a cautious attitude toward any interpretation applied to problems of human epidemiology. The general character of the epidemic process, as revealed in herds of mice living in close and continuous contact and subject to the continuous or intermittent migration of susceptibles, reveals that the disease, under these circumstances, will never normally die out. The form of the mortality curve depends, in the main, on the rate of immigration. The average death rate over any long period is probably not highly correlated with the immigration rate. The condition of equilibrium, though it may be continued for long periods, is fundamentally unstable and may be seriously disturbed by some extrinsic or intrinsic factor. In epidemics initiated by virulent and infective strains of *Bacterium aertrycke*, *Pasteurella muriseptica* or the virus of ectromelia, the rate of mortality during the early days of herd life is high. At later cage ages the level of mortality decreases. The expectation of

1. Greenwood, Major; Hill, A. B.; Topley, W. W. C., and Wilson, J.: *Experimental Epidemiology*: Medical Research Council Special Report Series, No. 209, London, His Majesty's Stationery Office, 1936.

life of the surviving mice rises continuously after the twentieth to thirtieth day of cage life, which, while greatly in excess of that of new entrants, never reaches the limited expectation of life of normal mice living in the same environment but not exposed to contact with an infective disease. It seems certain that selection, both by death of the more susceptible and by natural immunization, plays a part in the increased resistance of surviving mice. No evidence is obtainable that any change in the standard diet exerts a favorable influence on the course of mortality, although a known effect of A avitaminosis in lowering the resistance of animals cannot be denied. The experiments concerning the influence of bacteriophage on mouse typhoid yielded entirely negative results.

The carefully developed technic, the close control and the conservatism in interpreting their results in the light of human epidemics are especially commendable in this important contribution. It is a well balanced, stimulating study.

### Current Comment

#### "HEALTH ADVICE SHOULD BE AS FREE AS AIR AND WATER"

The title here quoted appears as that of an editorial by Bernarr Macfadden in his magazine called *Liberty*. Our old friend who used to exalt muscles is now worried because people let money creep into their affairs. He says "we have allowed business to creep into everything." He worries because there is business in religion and even romance is often commercialized. "There are women," he says, "who go into court and sue for breach of promise." He even mentions the fact that if a woman loses her husband as a result of romantic attraction from some other source there is often a suit for money damages! Now those familiar with newspaper records of old "bodylove" Macfadden's career in the courts devoted to marital upsets will realize that thus far he has been talking right out of his own experience. But he turns his attention next to the matter of health and disease and he insists that "the healers, whether osteopaths, chiropractors, or whatever they be—should be paid by the government." He doesn't like competition between various systems of doctoring. He thinks that with competition removed "all would work together for the purpose of making the patient healthy and strong." He says that "for more than fifty years" he has "been teaching health building and many of the simple procedures that have proved invaluable are not recognized by the public. People everywhere should have the advantage of these invaluable truths." O. K., Mr. Bernarr Macfadden! Why not use part of the magnificent Macfadden fortune, erected by the sale of physical culture hokum to the suckers who purchased the Macfadden courses, and the "dumbbells" who purchased the dumb-bells and the nature cure addicts who purchased the nostrums—why not use that now to give away these marvelous truths and procedures to all the people? If health advice—

even the kind of bad advice you have been selling—should be as free as air and water, why don't you give them yours instead of selling it? Maybe, after all, Mr. Macfadden, muscle and not mind or morals is your special field!

#### PARALYTIC AND PREPARALYTIC POLIOMYELITIS

According to a note in *Public Health Reports*,<sup>1</sup> two states have already instituted a classification for reporting cases of poliomyelitis into paralytic and preparalytic or nonparalytic types. The Department of Public Health of Massachusetts placed this classification in effect at the beginning of the present year. Effective October 20, a similar division was to be reported in the state of Tennessee. The number of cases of preparalytic poliomyelitis which are included in the total reported for that disease will be stated in each weekly report. These are nonfatal cases of poliomyelitis that have not shown definite muscular weakness. Because of the variability and uncertainty in recognition of nonparalytic poliomyelitis, it is believed that for recording and comparing intensity of spread of poliomyelitis only the paralytic cases should be counted when such distinction is possible. Any notable number of nonparalytic cases will be reported separately. There is no intention in this procedure to minimize the importance of the preparalytic or nonparalytic cases from the point of view of the spread of the disease or the necessity for medical care.

#### POLYAVITAMINOSIS AND ASULFUROSIS

The synergistic action of vitamins A and B has been recognized for a considerable period. A disease has been described which is distinct from pellagra and beriberi, is due to A and B avitaminosis and is characterized by lesions of the mucous membranes and skin, associated with or followed by disorders of the nervous system. Wright,<sup>1</sup> who has recently discussed the clinical and pathogenic aspects of this disorder, points out that the distribution of the epithelial lesions, which are the earliest evidence of the disease, is important. The tongue, lips, angles of the mouth, scrotum or vulva, and conjunctiva are the sites of earliest predilection. The reason for this localization, he believes, is that these are the areas richest in certain special cutaneous sense organs called end-bulbs, which are also found in the sheaths of nerve trunks, synovial membranes and intestinal mucosa. These end-bulbs are sense organs, composed of modified epithelial cells, in which the delicate terminations of the nerve filaments end. Observations on prisoners in the Freetown Gaol in Sierra Leone indicate that a diet containing an excess of starches tends to produce evidence of this clinical syndrome. Furthermore, prompt cure could be obtained by increasing either of the vitamins or the two together. Because of the evidence that lack of sulfur also plays a part in the deficiency, it was decided to use organic sulfur as a therapeutic agent in the treatment of "A and B avitaminosis disease" in Sierra Leone. Response of some of the patients to sulfur therapy was prompt

1. Paralytic and Nonparalytic (Preparalytic) Poliomyelitis, *Pub. Health Rep.* 51: 1556 (Nov. 6) 1936.

1. Wright, E. J.: Polyavitaminosis and Asulphurosis, *Brit. M. J.* 2: 707 (Oct. 10) 1936.

and significant. In fact, some relapsed patients showed a cure with sulfur even while continuing on the diet and under the same conditions in which the relapse occurred. The author concluded that vitamins A and B are interdependent for their efficient functioning; an excess of a cereal, not containing a cyanogen group, added to a balanced diet can precipitate avitaminosis; vitamins A and B can remain inactive in the organism if its sulfur content falls below a certain level; and, finally, great benefit to the patients and economy in treatment result from judicious sulfur therapy.

## Association News

### ANNUAL CONGRESS ON MEDICAL EDUCATION AND LICENSURE

The Annual Congress of the Council on Medical Education and Hospitals of the American Medical Association will be held at the Palmer House, Chicago, Feb. 15 and 16, 1937. The Federation of State Medical Boards of the United States will participate in the congress. The program follows:

#### MONDAY MORNING, FEBRUARY 15

- Report of the Council on Medical Education and Hospitals*  
Ray Lyman Wilbur, M.D., LL.D., Chairman, Stanford University, Calif.
- The Regulation of the Professions in the Public Interest*  
William E. Wickenden, B.S., President, Case School of Applied Science, Cleveland.
- What is a Profession?*  
Guy Stanton Ford, Ph.D., Dean, University of Minnesota Graduate School, Minneapolis.
- The Medical School Survey*  
Herman G. Weiskotten, M.D., Dean, Syracuse University College of Medicine, Syracuse, N. Y.

#### MONDAY AFTERNOON, FEBRUARY 15

- Report of the Survey to Individual Schools*  
William D. Cutter, M.D., Secretary, Council on Medical Education and Hospitals of the American Medical Association, Chicago.

#### SYMPOSIUM ON CANCER

- Biology of Cancer*  
C. C. Little, Sc.D., Director, Roscoe B. Jackson Memorial Laboratory, Bar Harbor, Maine.
- Pathology of Cancer*  
Francis Carter Wood, M.D., Director, Institute of Cancer Research, Columbia University College of Physicians and Surgeons, New York.
- The Teaching of Cancer*  
Frank E. Adair, M.D., Secretary, American Society for the Control of Cancer, New York.

#### TUESDAY MORNING, FEBRUARY 16

JOINT SESSION WITH THE FEDERATION OF STATE MEDICAL BOARDS OF THE UNITED STATES

#### SYMPOSIUM ON THE SELECTION OF STUDENTS

- Measurement of Personality*  
L. L. Thurstone, Ph.D., Professor of Psychology, University of Chicago.
- E. K. Strong Jr., Ph.D., Professor of Psychology and of Applied Psychology, Stanford University Graduate School of Business, Stanford University, Calif.
- Attitude Test*  
Torald Sollmann, M.D., Dean, Western Reserve University School of Medicine, Cleveland.
- Philosophical Comments on Examinations*  
Howard T. Karsner, M.D., Director, Institute of Pathology, Western Reserve University, Cleveland.
- Fundamental Purposes, Methodology and Technique of Examining in Relation to Medical Education and Licensure*  
Ben D. Wood, Ph.D., Associate Professor of Collegiate Educational Research, Teachers College, Columbia University, New York.
- A Better Type of Examination*  
Robert P. Dobbie, M.D., Assistant Professor of Surgery, University of Buffalo School of Medicine, Buffalo, N. Y.

#### TUESDAY AFTERNOON, FEBRUARY 16

- [Subject to be announced]  
Max Mason, Ph.D., California Institute of Technology, Pasadena, Calif.
- Relation of the American Medical Association to the Certification of Specialists*  
Charles Gordon Heyd, M.D., President, American Medical Association, New York.

#### Increase in the Number of Practitioners in the Country

Harold Rypins, M.D., Secretary, New York Board of Medical Examiners, Albany.

#### Grodnote Instruction in Idaho

Charles R. Scott, M.D., Twin Falls, Idaho.

#### THE FEDERATION OF STATE MEDICAL BOARDS OF THE UNITED STATES

#### MONDAY AFTERNOON, FEBRUARY 15

- Medical Licensure as Related to the Practice of Medicine*  
Edward H. Cary, M.D., Chairman, Committee on Legislative Activities of the American Medical Association, Dallas, Texas.
- The Doctor and the Narcotic Violator*  
R. L. Sensenich, M.D., President, Indiana State Medical Association, South Bend.
- A Lawyer's Point of View on the Narcotic Problem*  
Herman B. Carlson, Attorney, Iowa Board of Medical Examiners, Des Moines.
- Medical Licensure Problems in New England*  
Edward A. Knowlton, M.D., Member, Massachusetts Board of Registration in Medicine, Holyoke.

#### MONDAY EVENING, FEBRUARY 15

#### FEDERATION DINNER

#### Address of the President

J. N. Baker, M.D., Secretary, Alabama Board of Medical Examiners, Montgomery.

#### Address: Licensure and the Organized Profession

Charles Gordon Heyd, M.D., President, American Medical Association, New York.

#### Address: "Troil of the Adjuster"

Thomas J. Crowe, M.D., Secretary, Texas Board of Medical Examiners, Dallas.

#### Round Table Discussion

#### TUESDAY MORNING, FEBRUARY 16

JOINT SESSION WITH THE COUNCIL ON MEDICAL EDUCATION AND HOSPITALS OF THE AMERICAN MEDICAL ASSOCIATION

SYMPOSIUMS ON THE SELECTION OF STUDENTS AND THE TECHNIC OF EXAMINATIONS

#### TUESDAY NOON, FEBRUARY 16

#### Federation Luncheon

#### Executive Session

### THE ATLANTIC CITY SESSION

#### Appointment of Section Representatives to Scientific Exhibit

The following representatives from the various sections of the Scientific Assembly have been appointed to the Scientific Exhibit for the Atlantic City session:

#### PRACTICE OF MEDICINE:

Fred M. Smith, Iowa City.

#### SURGERY, GENERAL AND ABDOMINAL:

Lester R. Whitaker, Boston.

#### OBSTETRICS, GYNECOLOGY AND ABDOMINAL SURGERY:

H. Close Hesseltine, Chicago.

#### OPHTHALMOLOGY:

Georgianna Dvorak-Theobald, Oak Park, Ill.

#### LARYNGOLOGY, OTOTOLOGY AND RHINOLOGY:

Louis J. I. Burns, Philadelphia.

#### PEDIATRICS:

F. Thomas Mitchell, Memphis, Tenn.

#### PHARMACOLOGY AND THERAPEUTICS:

Wallace M. Yater, Washington, D. C.

#### PATHOLOGY AND PHYSIOLOGY:

F. W. Konzelmann, Philadelphia.

#### NERVOUS AND MENTAL DISEASES:

Peter Bassoe, Chicago.

#### DERMATOLOGY AND SYPHILOLOGY:

Clark W. Finnerud, Chicago.

#### PREVENTIVE AND INDUSTRIAL MEDICINE AND PUBLIC HEALTH:

Paul A. Davis, Akron, Ohio.

#### UROLOGY:

R. S. Ferguson, New York.

#### ORTHOPEDIC SURGERY:

Jesse T. Nicholson, Philadelphia.

#### GASTRO-ENTEROLOGY AND PROCTOLOGY:

J. A. Bargaen, Rochester, Minn.

#### RADIOLOGY:

E. E. Downs, Woodbury, N. J.

Application blanks for space in the Scientific Exhibit may be obtained from any of these representatives or from the Director, Scientific Exhibit, 535 North Dearborn Street, Chicago.

## RADIO BROADCASTS

The American Medical Association and the National Broadcasting Company are presenting the second series of dramatized health broadcasts under the title *Your Health*. The first broadcast in the new series, the thirty-second dramatized cooperative broadcast under the title *Your Health*, was given October 13. The theme for 1936-1937 differs slightly from the topic in the first series, which was "medical emergencies and how they are met." The new series is built around the central idea that "100,000 American physicians in great cities and tiny villages, who are members of the American Medical Association and of county and state medical societies, stand ready, day and night, to serve American people in sickness and in health."

The program will go out on the Blue network instead of on the Red network, as originally announced.

The topics are announced monthly in advance in *Hygeia*, the Health Magazine, and three weeks in advance in each issue of *THE JOURNAL*. The topics and speakers for the next three programs are:

- December 15. Milk. W. W. Bauer, M.D.
- December 22. The Gift of Health. Morris Fishbein, M.D.
- December 29. Health Assets and Liabilities. W. W. Bauer, M.D.

The time of the broadcast is Tuesday afternoon at 4 o'clock central standard time (5 o'clock eastern time, 3 o'clock mountain time, 2 o'clock Pacific time).

## Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

## ARKANSAS

**Lectures on Obstetrics.**—A postgraduate course in obstetrics will be conducted in Arkansas, under the auspices of the U. S. Children's Bureau, the state medical society and the state board of health. Dr. M. Edward Davis, associate professor of obstetrics and gynecology of the Division of Biological Sciences, University of Chicago, will be the lecturer. His schedule is as follows:

- |                            |                             |
|----------------------------|-----------------------------|
| Jonesboro, January 4-8.    | Hope, February 8-12.        |
| Harrison, January 11-15.   | Monticello, February 15-19. |
| Fort Smith, January 18-22. | Conway, February 22-26.     |

The subjects will include the treatment of hemorrhage in pregnancy; antepartum care and the toxemias of pregnancy; puerperal infection, its prophylaxis and treatment; management of breech presentation and management of labor in the contracted pelvis, and forceps delivery.

## DELAWARE

**Health at Wilmington.**—Telegraphic reports to the U. S. Department of Commerce from eighty-six cities with a total population of 37 million indicate that the highest mortality rate (20.6) for the week ended November 28 appeared for Wilmington and that the rate for the group of cities as a whole was 11.5. The mortality rate for Wilmington for the corresponding period last year was 8.3 and for the group of cities, 11.1. The annual rate for eighty-six cities for the forty-eight weeks of 1936 was 12, as against a rate of 11.3 for the corresponding period of the previous year. Caution should be used in the interpretation of these weekly figures, as they fluctuate widely, and the death rate may tend to be increased in cities that are hospital centers or that have a large population of Negroes.

## ILLINOIS

**Society News.**—The second annual meeting of the members of the American College of Physicians of the state of Illinois, outside of Chicago, was recently addressed in Peoria by Drs. Allen K. Krause, Baltimore, on "Future Possibilities of the Diagnosis of Tuberculosis"; Horace W. Soper, St. Louis, "Clinical Significance of Milk and Cholesterol in the Dietary of Man," and Frank Smithies, Chicago, "Certain Ulcerative Lesions of the Bowel, Their Recognition and Management."—At a meeting of the Adams County Medical Society in Quincy, November 9, Dr. Carl F. Vohs, St. Louis, discussed

"Medical Security for the People by the Profession," and Mr. Ray F. McCarthy, St. Louis, "Interpreting Medical Leadership by the Profession."

## Chicago

**Meetings of Branch Societies.**—Dr. Howard K. Gray, Rochester, Minn., discussed "Surgery of Peptic Ulcer and Its Complications" before the Evanston Branch of the Chicago Medical Society, December 3, and Dr. Arthur R. Colwell, Evanston, Ill., "The Use of Protamine Insulin in the Treatment of Diabetes."—At a meeting of the North Side Branch, December 3, Dr. James B. Herrick read a paper entitled "Dr. Charles T. Parkes as I Knew Him," and Dr. Austin A. Hayden, "Biography of Charles T. Parkes." Drs. Frederick W. Madison and Theodore L. Squier, Milwaukee, discussed "The Role of Sensitivity to Drugs in the Production of Agnucyctosis."—Dr. Julius H. Hess addressed the Englewood Branch on "Clinical Procedures in Pediatric Practice," December 1.—At a meeting of the North Shore Branch, December 1, the speakers included Drs. Herbert A. Sacks on "Crisis in Addison's Disease Simulating Coronary Thrombosis" and Robert W. Keeton, "Problems in Malnutrition."

**State Commanders' Meeting.**—State commanders from ten Central Western states organized in the Women's Field Army of the American Society for the Control of Cancer met at the Chicago Woman's Club, November 30, to discuss plans for "enlistment week," March 21-27. "Early cancer is curable; fight it with knowledge" is the slogan of the field army, which seeks to enroll members for an enlistment fee of \$1. The money will be used to defray the expenses of disseminating information about cancer. It is hoped that this educational campaign will bring early cases to competent physicians for treatment. Speakers at the meeting included Mrs. Grace Morrison Poole, national adviser of the army; Dr. James P. Simonds, professor of pathology, Northwestern University School of Medicine, and Dr. Frank L. Rector, Evanston, field representative of the American Society for the Control of Cancer. Commanders were present from Colorado, Indiana, Kansas, Kentucky, Illinois, Michigan, Minnesota, Nebraska, Wisconsin and South Dakota.

## INDIANA

**First Medicolegal Conference.**—Scientific methods of criminal investigation and the coordination of medical and legal efforts in criminal and civil procedure were considered at Indiana's first medicolegal conference, December 4, at the Indiana University Medical Center, Indianapolis. The conference was sponsored by the medical school, the state police department, the university's institute of criminal law and criminology and the Indiana Committee, a group of citizens interested in law enforcement and improvement of criminal law administration. Laboratory work of the university's departments of toxicology, biochemistry, pathology and psychiatry and that of the state police laboratory was demonstrated, and the question of employment of medical examiners selected on the basis of their special qualifications for criminal investigative work was discussed. Chemical tests for intoxication with special regard to automobile and industrial accidents were discussed by Rolla N. Harger, Ph.D., professor of biochemistry and toxicology, Indiana University School of Medicine; Clarence W. Muehlberger, Ph.D., Chicago, coroner's toxicologist of Cook County; Kenneth H. Kohlstaedt, assistant superintendent of the Indianapolis City Hospital; Dr. Ethelbert R. Wilson, coroner-elect of Indianapolis, and Lieut. Don L. Kooker of the state police. Another session was devoted to a consideration of "The Expert Medical Witness, with Special Regard to Questions of Insanity, Psychiatric Assistance and Reliability of Testimony." Other speakers on the program included E. P. Coffey, chief of the federal crime detection laboratory, Washington, D. C.; Hugh McK. Landon, president of the Indiana Committee; Dr. Willis D. Gatch, dean of the medical school; Dr. Frank Forry, head of the department of pathology; Dr. Clyde Gray Culbertson, head of the central laboratory at the medical center; Prof. James J. Robinson, director of the institute of criminal law and criminology; Albert L. Rabb, member of the state police board; Joseph J. Daniels of the Indianapolis Bar Association, and James A. Collins, former judge of the Marion County Criminal Court.

## KANSAS

**Venereal Disease Committee.**—Dr. Arthur D. Gray, Topeka, has been appointed chairman of a committee on venereal disease recently created by the Kansas Medical Society. Other members include Drs. Robert M. Brian and Glen E. Kassebaum, El Dorado; Oscar W. Davidson, Kansas City; Henry Haerle, Marysville; James E. Henshall, Osborne; Oliver

W. Miner, Garden City; Harold F. O'Donnell, Wichita; Chester O. Shepard, Independence; Walter J. Singleton, LaCrosse, and Leslie C. Tilden, Oberlin. The establishment of the committee followed a conference between representatives of the state medical society and the state board of health. The committee will act in an advisory capacity to the state board of health in the development of programs throughout Kansas.

### MAINE

**Society News.**—At a meeting of the Hancock County Medical Society in Ellsworth, October 21, Drs. Frederick T. Hill, Waterville, president of the Maine Medical Association, discussed acute conditions of the throat; Philip L. Gray, South Brooksville, "Uses of Barbitol and Its Derivatives in General Medicine."—Dr. Laforest J. Wright, Bangor, read a paper before the Oxford County Medical Association in Bethel, October 13, entitled "The Foot and the Shoe."—The Penobscot County Medical Society was addressed, October 27, by Dr. William B. Castle, Boston, on "Rational Treatment of Anemias."—At a meeting of the Somerset County Medical Society in Bingham, October 22, Dr. Charles Ayers, Worcester, Mass., discussed "Lumbosacral Diseases and Sciatica."

### MASSACHUSETTS

**Lessons in Parliamentary Law.**—The Wachusett Medical Improvement Society announces a course of four lessons in parliamentary law for physicians at the Holden District Hospital by Charles W. Proctor, Esq. The first lecture was given November 25 on "Parliamentary Conduct of Members at Meetings."

**Williams Memorial Lecture.**—The Henry Willard Williams Memorial Lecture will be delivered at the Boston City Hospital, December 16, by Dr. Allen Greenwood, professor of ophthalmology, emeritus, Tufts College Medical School, on "History of Ophthalmology in New England." Dr. Benjamin Sachs, professor of ophthalmology at Tufts, will preside.

### MICHIGAN

**Personal.**—David Judson Lingle, Ph.D., associate emeritus professor of physiology, University of Chicago, died in Rapid City, November 20, aged 73. Dr. Lingle until his retirement in 1925 had been a member of the university faculty for thirty-three years and was known for his research on the heart and the circulatory system.—Dr. John McLean, Hartford, observed his ninety-seventh birthday November 14.—Dr. Thomas E. Camper, Camden, N. J., has been appointed health officer of Iron County.

**Forum on Medical Economics.**—The relation of social security to the practice of medicine was the theme of a panel discussion in Detroit, December 9, under the auspices of the medical economics committee of the Wayne County Medical Society and the Michigan State Medical Society. Speakers included:

William Haber, professor of economics, University of Michigan, Ann Arbor, and state relief administrator.

Robert W. Kelso, director, Institute of Public and Social Administration, University of Michigan, Ann Arbor.

Rev. Frederic Siedenberg, S.J., executive dean, University of Detroit, and president of state conference of social workers.

S. S. Skelton, director of welfare for Oakland County.

Dr. Frederick A. Baker, Pontiac, member of the Council of the Michigan State Medical Society.

Dr. Stanley W. Insley, Detroit, member, relief study commission.

Dr. Henry A. Luce, Detroit, member, House of Delegates, American Medical Association.

Dr. J. Milton Robb, Detroit, past president, state medical society.

### MINNESOTA

**Illegal Practitioner Ordered Out of State.**—Henry Jeffrey, Armstrong, pleaded guilty to two complaints charging him with practicing healing without a basic science certificate, November 24, before Judge L. H. Morse of the municipal court at Mankato. Jeffrey was fined \$100 on the first complaint; he paid the fine, and the jail sentence of ninety days received on the second complaint was suspended. Jeffrey represented himself as "Dr." Jeffrey. In September he treated a Mankato woman, suffering with tuberculosis, for asthma, and prescribed several kinds of roots and herbs. At the time of his arrest, the back of his automobile was filled with boxes and packages of roots and herbs, pill and salve boxes and empty bottles, with duplicate sheets containing directions for the various preparations; his customary charge was \$15 at the time of his first call and \$10 a month thereafter. He was told to stay out of Minnesota for one year.

### MISSISSIPPI

**Society News.**—Dr. Henry King Wade, Hot Springs National Park, Ark., addressed the Delta Medical Society in Belzoni, October 14, on "Gonorrheal Epididymitis and Its Treatment," among others.—The Issaquena-Sharkey-Warren Counties Medical Society was addressed, December 8, at Vicksburg, among others, by Drs. Waltman Walters, Rochester, Minn., on "Surgical Lesions of the Biliary Tract with Special Reference to Recent Studies in Obstructive Jaundice," and James M. Mason, Birmingham, Ala., "Diverticulitis of the Ileum."

### NEW YORK

**Tests of Dust Control Apparatus.**—The state department of labor recently set up a field laboratory at a granite quarry at Letchworth Village, Rockland County, to test several types of dust control equipment which will be made available for commercial use in compliance with antisliposis legislation adopted last year. The Rockland County granite is said to have a high silica content which will afford an effective test for the equipment. Dr. John J. Lloyd, Rochester, was recently named a member of the special board authorized in the new law to act as consultants on dust diseases for the state department of labor. Drs. Edgar Mayer and James Burns Amberson Jr., New York, are the other consultants.

### New York City

**Third Harvey Lecture.**—The third Harvey Society Lecture of the year will be given by Dr. Stephen W. Ranson, professor of neurology and director of the institute of neurology, Northwestern University Medical School, Chicago, at the New York Academy of Medicine, December 17, on "Some Functions of the Hypothalamus."

**Personal.**—Dr. Thomas M. Rivers of the Rockefeller Institute for Medical Research received the honorary degree of doctor of science at the centennial convocation of Emory University, Atlanta, December 12.—A gold medal was recently presented to Dr. Joseph Tenopir, chairman of the medical board of the Caledonian Hospital, Brooklyn, in appreciation of his services to the hospital. He has been associated with the hospital since 1917 and chairman of the medical board for six years.—Dr. Robert Gutierrez addressed the French Urological Congress during its annual congress in Paris, October 5-10, on "The Role of Anomalies of the Kidney and Ureter in the Causation of Surgical Conditions."—Dr. Ephym E. Syrkin has been appointed executive director of the Beth Moses Hospital, Brooklyn, to succeed Dr. Milton L. Dryfus, who retired November 1.

**Society News.**—Dr. Charles Gordon Heyd, President of the American Medical Association, addressed the Medical Society of the County of Queens, November 24, on "Organized Medicine—A Service to the Community." The society met jointly with the dental profession of Queens County, November 30, with the following speakers: Dr. William J. Hoffman, "The Relationship of Dentistry to Intra-Oral Cancer"; Louis I. Abelson, D.D.S., "Medicodental Cooperation in Everyday Practice as Related to Office Practice"; Dr. Arthur J. Horton, Halli, N. Y., "Focal Infection and Its Relation to Systemic Diseases," and Dr. Morris I. Schamberg, "Medicodental Cooperation in Everyday Practice as Related to Hospital Practice."—Dr. Henry C. Eichacker addressed the Queensboro Surgical Society, November 16, on "Fibromyomas Complicating Pregnancy."—Drs. Irving H. Pardee and Ira I. Kaplan addressed the New York Endocrinological Society, November 25, on "A New Pituitary-Parathyroid Syndrome" and "Radiation Therapy in Endocrine Disorders" respectively.—Drs. Guilford S. Dudley and Laurence Miscal addressed the New York Surgical Society, November 25, on "Inflammatory Tumors of the Gastro-Intestinal Tract."—A symposium on the child and the adolescent was presented at the meeting of the International Spanish-Speaking Association of Physicians, Dentists and Pharmacists, November 27, by Drs. George W. Crile, Cleveland; Edward L. Bauer, Philadelphia; Guillermo Brinck, University of Santiago, Chile; Henry Keller, Richard L. Frank and Charles G. Kerley.

### NORTH CAROLINA

**Society News.**—Dr. Cecil C. Swann, Asheville, addressed the Buncombe County Medical Society, Asheville, October 19, on "Allergy in Relation to Otolaryngology."—The Seventh District Medical Society held a meeting at Gastonia, October 29, with Dr. Louis Hamman, Baltimore, as guest clinician. Among other speakers were Drs. William C. Bostic Jr., Forest City, on "The Poisonous Spiders"; Thomas C. Bost, Charlotte,

"Lowering the Mortality in Intestinal Obstruction," and S. E. Moser, D.D.S., Gastonia, "Diagnosis and Treatment of Vincent's Infection."

## OHIO

**Personal.**—Dr. and Mrs. Charles R. Ziegler, Carrollton, celebrated the sixtieth anniversary of their marriage November 9. Dr. Ziegler was graduated from Jefferson Medical College, Philadelphia, in 1874, and has practiced in Carrollton since 1885.—Dr. Richard S. Austin has been appointed to the Cincinnati Board of Health to succeed the late Dr. William B. Wherry.

**Physicians Honored for Long Service.**—Four physicians were guests of honor at a luncheon meeting of the Highland County Medical Society in Hillsboro, November 11, in recognition of their long records of medical practice: Drs. Robert J. Jones and John A. Mercer, Greenfield, John C. Larkin, Hillsboro, and Thomas W. Roberds, Belfast. All have practiced for more than forty years. Dr. John D. McBride, Hillsboro, presided and the speakers were Drs. Edwin M. Huston, Dayton, president of the Ohio State Medical Association; John A. Caldwell, Robert Carothers and Parke G. Smith, all of Cincinnati.

## OKLAHOMA

**Society News.**—Drs. Victor K. Allen, Tulsa, and Horace Reed, Oklahoma City, addressed the Kay County Medical Society, Ponca City, October 15, on "Hemorrhoids and Their Treatment" and "Anesthesia and Abdominal Surgery from the Surgeon's Viewpoint" respectively.—Drs. William L. Bonham and Minard F. Jacobs, Oklahoma City, addressed the Okmulgee-Okfuskee Counties Medical Society in Henryetta, October 19, on "Diseases of the Floor of the Mouth" and "Chronic Ulcerative Colitis" respectively.—A symposium on pain in the back was presented before the Tulsa County Medical Society, Tulsa, November 23, by Drs. Pierre N. Charbonnet, Frank A. Stuart Jr., Ned R. Smith and Henry S. Browne.

## OREGON

**University Faculty Changes.**—Dr. Edwin E. Osgood, assistant professor of biochemistry and medicine, University of Oregon Medical School, Portland, has been appointed head of a newly established division of experimental medicine. Dr. J. Guy Strohm has been made clinical professor of urology and acting head of the division of urology and Dr. William K. Livingston has been appointed assistant professor of surgery.

## PENNSYLVANIA

**Society News.**—Dr. Joseph V. Missett Jr., Philadelphia, addressed the Dauphin County Medical Society, Harrisburg, November 3, on "Hemorrhage Complicating Late Pregnancy."—Dr. James M. H. Rowland, Baltimore, will address the Harrisburg Academy of Medicine, December 15, on "Accidental Complications of Pregnancy, Stressing Heart Disease and Tuberculosis."—Dr. Joseph H. Barach, Pittsburgh, addressed the Medical Society of Franklin County at Chambersburg, November 17, on hypertension.

## Philadelphia

**Hospital News.**—The twenty-fifth anniversary of the founding of the Babies' Hospital of Philadelphia was celebrated at a dinner, November 17, at which the speakers included Drs. Philip Van Ingen, New York, and Borden S. Veeder, St. Louis.

**Society News.**—At a meeting of the Philadelphia Clinical Association, December 1, the speakers were Dr. Leopold S. Vaccaro, on "The Medicolegal Aspects of the Pennsylvania Compensation Act and Its Need for Liberalization," and Mr. James M. Grundy, district representative of the state workman's insurance fund, "The Doctor and the Insurance Company in Insurance Cases."—A symposium on vaginal hysterectomy was presented at a meeting of the Obstetrical Society of Philadelphia, December 3, by Drs. Leonard Averett and John A. McGlenn; Dr. Newlin F. Paxson described English clinics.

## SOUTH CAROLINA

**Society News.**—The South Carolina X-Ray Society held its first annual meeting in Charleston, November 5. The speakers, all of Charleston, were Dr. Robert B. Taft, on super-voltage therapy installations; Drs. T. Hutson Martin and Augusta E. Willis, treatment of cancer of the breast; J. Hampton Hoch, Sc.D., effects of normal and abnormal irradiation; Dr. Hillyer Rudisill Jr., skin reaction and skin recovery; Dr. Thomas M. Peery, grading of tumors, and Dr. Harold Wood, microscopic changes in tumors following irradiation.

## TEXAS

**Faculty Changes at Baylor.**—Among changes announced at Baylor University School of Medicine, Dallas, at the opening of the school year were the following promotions:

Dr. Christopher B. Carter, to be associate professor of applied anatomy and clinical surgery.  
Dr. James H. Black, to be professor of clinical medicine (allergy).  
Robert W. Lackey, Ph.D., to be associate professor of physiology.  
Dr. Walter W. Brandes, to be associate professor of pathology.  
Dr. Robert F. Short, to be assistant professor of clinical surgery.  
Dr. J. Warner Duckett, to be assistant professor of clinical surgery.  
Dr. Oscar M. Marchman, to be associate professor of clinical otolaryngology.

**District Meetings.**—At the thirty-first annual meeting of the Fourth District Medical Society in San Angelo, October 21-22, the speakers included Drs. Maurice C. Barnes, Waco, on "Management of Allergic Patients"; Paul Gallagher, El Paso, "Empyema"; Lee J. Globber, San Antonio, "Treatment of Sterility," and Floyd T. McIntire, San Angelo, "Treatment of Pneumonia by X-Rays." Dr. Howard R. Dudgeon, Waco, president of the Texas State Medical Association, was the guest speaker, on "The Trend Toward Socialization of Medicine and How to Check It."—Speakers on the program of the Eleventh District Medical Society, October 13, included Drs. Joseph H. Paxton, Elkhart, on "Diagnosis of Cholecystitis and Cholelithiasis"; Jack F. Perkins, Dallas, "Diagnosis and Treatment of Oligemia and Oligocythemia," and Alfred I. Folsom, Dallas, treatment of gonorrhea in the male.

## WASHINGTON

**Society News.**—Dr. Claude E. Dolman, Vancouver, B. C., addressed the Pierce County Medical Society, Tacoma, October 13, on "Staphylococcus Toxoid."—Dr. Otis F. Akin, Portland, Ore., addressed the Walla Walla Valley Medical Society, Walla Walla, November 12, on "Foot Pains, Their Cause and Treatment from the General Practitioner's Viewpoint."—At a meeting of the Yakima County Medical Society, Yakima, October 12, the speakers, all of Seattle, were Drs. Ole A. Nelson, on "Cervical Infections in Relation to Urinary Tract Infections and Symptoms"; Delbert H. Nickson, "Pathology of Cervical Disease," and John E. Wirth, "Treatment of Carcinoma of the Cervix."

## WEST VIRGINIA

**Licensure of Foreign Physicians.**—The Public Health Council of West Virginia adopted a resolution recently governing the licensure of graduates of foreign medical schools. Under the regulation, which goes into effect January 1, a foreign graduate will have to prove that he is licensed to practice in the country of his graduation and that he has served a year's internship in an approved hospital or that he has completed the fourth year of medicine at an American class A medical college, as classified by the Council on Medical Education and Hospitals of the American Medical Association.

**Society News.**—Dr. I. Newton Kugelmass, New York, addressed the Ohio County Medical Society, Wheeling, November 6, on "Management of Hemorrhagic Diseases in Children."—Dr. Everett C. Drash, Charlottesville, Va., addressed the Mercer County Medical Society, Princeton, October 29, on "The Present Status of Thoracic Surgery."—Drs. Daniel P. Foster and Joseph A. Johnston, Detroit, addressed the medical societies of Marion, Harrison and Monongalia counties in Fairmont, October 27, on "Dietotherapy" and "Cerebral Hemorrhage in the New-Born" respectively.—Dr. Morris Fishbein, Chicago, editor of THE JOURNAL, will address the Grant-Hampshire-Hardy-Mineral Counties Medical Society, Romney, December 19, in a meeting with the Allegany-Garrett Counties Medical Society of Maryland.—Drs. Frank C. Hodges and Ray M. Bobbitt, both of Huntington, addressed the Cabell County Medical Society, November 12, on "Testicular Teratoma."—Drs. Herbert H. Haynes and Walter W. Spelsberg, Clarksburg, addressed the Central West Virginia Medical Society at Buckhannon in October on "Operations for Cancer of the Rectum" and "Conservative Diagnosis of Sinus Disease" respectively.—At a meeting of the Raleigh County Medical Society in Beckley, November 16, Dr. Roy M. Hoover, Roanoke, Va., spoke on "Ununited Fractures."

## WISCONSIN

**Society News.**—Dr. Edward A. Oliver, Chicago, addressed the Outagamie County Medical Society, Appleton, November 12, on dermatologic problems of the general practitioner.—Dr. Walter A. Schiller, Vienna, Austria, addressed the Brown-Kewaunee-Door Counties Medical Society, at Green Bay, November 7, on early diagnosis of cancer in women.

## GENERAL

**Science Exhibition.**—The annual science exhibition of the American Association for the Advancement of Science will be held in the Atlantic City Auditorium, December 28-January 1. The progress of science will be depicted in an illuminating manner by scientific groups, commercial exhibitors and the leading publishers of books, and many authors and writers in science will be present.

**Prize for Study on Goiter.**—The American Association for the Study of Goiter again announces a competition for the Van Meter prize of \$300 and two honorable mentions for the best essays submitted describing experimental and clinical investigations of the thyroid gland. The award will be made at the annual meeting of the association in Detroit, June 14-16, 1937. Manuscripts should be sent to the secretary, Dr. W. Blair Mosser, 133 Biddle Street, Kane, Pa., not later than April 1, 1937. They must be in English and typed double space.

**Academy of Tropical Medicine.**—Dr. Wilbur A. Sawyer, director of the International Health Division of the Rockefeller Foundation, New York, was elected president of the American Academy of Tropical Medicine at its third annual meeting in Baltimore, November 18. Dr. Ernest Muir, London, secretary of the British Empire Leprosy Relief Association, addressed the academy on "Recent Progress in Tropical Medicine in India." Dr. Richard P. Strong, Boston, retiring president, made his official address on "The Modern Period of Tropical Medicine."

**Society News.**—Dr. Mark F. Boyd, Tallahassee, Fla., was chosen president-elect of the American Society of Tropical Medicine at the annual meeting in Baltimore, November 18-20. Dr. Herbert C. Clark, Panama, R. P., was installed as president; Karl F. Meyer, Ph.D., San Francisco, was elected vice president, and Dr. Noel Paul Hudson, Columbus, Ohio, reelected secretary.—Dr. Frederic Brodie, Vancouver, B. C., was made president of the North Pacific Surgical Association at its twenty-fifth annual meeting in Tacoma, Wash., November 20-21. Other officers elected included Drs. Andrew A. Matthews, Spokane, Wash., first vice president; Gordon Kenning, Victoria, B. C., second vice president, and Karl H. Martzloff, Portland, Ore., secretary. Dr. Leo Eloesser, San Francisco, was the guest speaker.

**Changes in Status of Licensure.**—The Michigan State Board of Registration in Medicine reports the following action:

Dr. William D. Rea, Minneapolis, license revoked for unprofessional and dishonest conduct.

Dr. Douglas Hurst Radcliff, Detroit, license suspended until June 1937, pending a hearing when he will be cited to show cause why his medical license should not be revoked for his conviction of "the procuring, aiding or abetting in procuring a criminal abortion."

The Minnesota State Board of Medical Examiners, St. Paul, reports the following:

Dr. William M. Chowning, Minneapolis, license revoked November 7 for his conviction on the charge of abortion.

Dr. Frederic H. Moss, Roseville, Ill., license revoked November 7 for habitual indulgence in the use of narcotics.

The Colorado State Board of Medical Examiners reports the following action:

Dr. Earnest O. McCleary, Ordway, license restored.

**Grocers Make Award to Dr. Minot.**—The Associated Grocery Manufacturers Association of America, at their annual banquet on December 1 at the Waldorf-Astoria Hotel, New York City, presented to Dr. George R. Minot, Boston, their annual award for research in the field of nutrition leading to the prevention of disease and the advancement of health. The selection of Dr. Minot was made by the following advisory committee:

George R. Cowgill, Ph.D., Yale University, New Haven, Conn., chairman.

Dr. James S. McLester, Birmingham, Ala., Past President of the American Medical Association.

Dr. George W. McCoy, Director of National Institute of Health, United States Public Health Service, Washington, D. C.

Mary S. Rose, Ph.D., Columbia University, New York.

Leonard A. Maynard, Ph.D., Cornell University, Ithaca.

The presentation address was made by Dr. Morris Fishbein, Chicago, editor of THE JOURNAL.

**Diagnostic Atlas of Tumors.**—Announcement is made of the preparation of an "International Diagnostic Atlas of Tumors" under the direction of a committee of the International Union Against Cancer. The committee was originally appointed to consider standardization of nomenclature of neoplasms, but after several meetings it was decided that there would be no advantage in attempting to establish by fiat a standard nomenclature when specialists are not agreed about many designations. It was therefore agreed to publish the atlas showing photomicrographs of neoplasms and including in

the text the most frequently used names. The classification will be anatomic rather than by types of tumors. The volume will contain about 400 or 500 pages of halftones and an equal number of descriptive text. The expense of publication is to be borne by the Chemical Foundation. The probable price will be about \$8. Dr. Francis Carter Wood, New York, has been appointed editor for the English edition.

**Association for Research in Nervous and Mental Diseases.**—The annual meeting of the Association for Research in Nervous and Mental Diseases will be held at the Waldorf-Astoria in New York, December 28-29. The entire program of more than forty papers will be devoted to considerations of the pituitary gland. Among the speakers will be:

Dr. Frederick Tilney, New York, Glands of the Brain, with Special Reference to the Pituitary.

Andrew T. Rasmussen, Ph.D., Minneapolis, The Proportions of the Various Subdivisions of the Normal Adult Human Hypophysis Cerebri.

Dr. Herbert M. Evans, Berkeley, Calif., The Growth Hormone.

Dr. Hector Mortimer, Montreal, Skull Formation in Relation to the Pituitary Gland.

Dr. Cyril N. H. Long, New Haven, Conn., Carbohydrate Metabolism in Relation to the Pituitary Gland.

Dr. James B. Collip, Montreal, Antihormones.

Dr. Louis A. Lurie, Cincinnati, Pituitary Disturbances in Relation to Personality.

Dr. Gilbert Horrax, Boston, Surgical Treatment of Pituitary Neoplasms.

Dr. Eberle Kost Shelton, Santa Barbara, Calif., Pituitary Dwarfism.

**Conference on College Hygiene.**—The second National Conference on College Hygiene will be held in Washington, D. C., December 28-31, at the Wardman Park Hotel. The conference aims to bring up to date information relating to the findings and recommendations of the first conference, which was held in 1931 at Syracuse University. The sessions will be discussion meetings with no prepared addresses. The work is divided into five sections with chairmen as follows: health service, Dr. Warren E. Forsythe, Ann Arbor, Mich.; health teaching, Mrs. Kathleen W. Wootten, Georgia State College for Women, Milledgeville; organization and correlation, Dr. Thomas A. Storey, Stanford University, Calif.; special problems, Dr. Jesse F. Williams, Columbia University, New York, and relation of college hygiene to teacher training and secondary schools, Dr. John Sundwall, Ann Arbor, Mich. The conference is under the sponsorship of the American Student Health Association, the Presidents' Committee of Fifty on College Hygiene and the National Health Council. Dr. Livingston Farrand, president of Cornell University, Ithaca, is president of the conference and Dr. Hugh S. Cumming, former surgeon general of the U. S. Public Health Service, is chairman of the local committee on arrangements.

**Southern Surgical Association.**—The forty-ninth annual session of the Southern Surgical Association will be held at the Edgewater Gulf Hotel, Edgewater Park, Miss., December 15-17. Guest speakers listed on the program include:

Dr. George J. Heuer, New York, Surgical Treatment of Cholecystitis.

Dr. Frank H. Lahey, Boston, Strictures of the Common and Hepatic Duct.

Dr. Frederick A. Collier, Ann Arbor, Mich., Treatment of Typhoid Carriers by Cholecystectomy.

Dr. John deJ. Pemberton, Rochester, Minn., Regional Ileitis.

Dr. William L. Estes Jr., Bethlehem, Pa., Enteritis of the Obstructed Loop After Entero-Anastomosis for Intestinal Obstruction.

Dr. Willis D. Gatch, Indianapolis, The Technic of Closing Perforated Ulcer of the Duodenum.

Dr. Donald C. Balfour, Rochester, Minn., Factors of Significance in the Prognosis of Cancer of the Stomach.

Dr. Roy D. McClure, Detroit, A Study of 252 Consecutive Cases of Acute Perforated Appendicitis with Peritonitis.

Dr. Mont R. Reid, Cincinnati, Wound Healing.

Dr. Donald Guthrie, Sayre, Pa., Dangers of Avertin Anesthesia.

The association dinner will be held Wednesday evening, with Dr. Hubert A. Royster, Raleigh, N. C., as toastmaster. Dr. Harvey B. Stone, Baltimore, will give the presidential address on "Wider Horizons for the Surgeons." There will be a golf tournament on the Edgewater Gulf Course, Tuesday afternoon.

---

Government Services

## Captain Armstrong Wins Wellcome Prize

Captain Harry G. Armstrong, U. S. Army Medical Corps, director of the physiologic research laboratory at Wright Field, Dayton, Ohio, was awarded the Wellcome Prize at the annual meeting of the Association of Military Surgeons of the United States for an essay on "The Importance of Coordinating the Military and Naval Medical Services with the Civilian Medical Profession." The prize of \$500 and a gold medal were presented at the annual meeting of the association in Detroit, October 29-31. Captain Armstrong was graduated from the University of Louisville School of Medicine in 1925.

## Foreign Letters

### LONDON

(From Our Regular Correspondent)

Oct. 31, 1936.

#### The British Pharmacopeia

A new edition of the British Pharmacopeia is published every ten years. In the interval the work is kept down to date by the issue of addenda from time to time. An addendum containing important new material is announced by the Pharmacopeia Commission, which has found it necessary to exclude on account of proprietary monopolies or restrictions certain drugs that otherwise might have been included. Two pentavalent arsenical compounds—acetarsol for oral administration and tryparsamide for subcutaneous injection—are added. For cod liver oil a minimum standard of 600 units of vitamin A activity and 85 of antirachitic is now required. Vitamin B is represented by pulvis vitaminii B<sub>1</sub>, an adsorbate of the antineuritic vitamin on fuller's earth, containing in 1 Gm. 100 units of antineuritic activity. Vitamin C is described as ascorbic acid (cevitamic acid) and must contain not less than 98 per cent of the pure compound as ascertained by titration with iodine. Vitamin D is now represented by calciferol, obtained by ultraviolet irradiation of ergosterol. One mg. has to contain 40,000 units of antirachitic activity. Five new preparations of antitoxins and serums are described. Serum, dried serum, solution of antitoxic globulins and dried antitoxic globulins are recognized. Antitoxinum oedematiens contains the specific antitoxic globulins against the toxin of *Clostridium oedematiens*; antitoxinum staphylococcicum, against certain strains of staphylococcus; antitoxinum vibriosepticum, against *Clostridium*, generally known as "vibrio septique." Antipneumococcus serums for type I and type II are given and the dosage in each case is from 50 to 150 thousand units. Two new compounds of bismuth are introduced in view of the use of injections—bismuth and sodium tartrate (containing from 35 to 42 per cent of bismuth) and bismuth oxychloride (containing from 79 to 81 per cent). The recent work on ergot is recognized by including the alkaloid ergometrine (ergonovine), for which the oral dose is from  $\frac{1}{120}$  to  $\frac{1}{60}$  grain (0.5 to 1 mg.). An organic mercurial diuretic, mersalyl, a sodium salt of a salicyl compound, is given. Chiniofon, a drug for the treatment of tropical dysentery, is described as a mixture of four parts of iodohydroquinoline sulfonic acid and one part of sodium bicarbonate. Citrated ferrous chloride, of which the dose is from 3 to 5 grains (0.2 to 0.3 Gm.) is introduced to supply a stable form of ferrous chloride which can be compressed into tablets. Sodium thio-sulfate is introduced on account of its use in the treatment of toxic effects from arsenical drugs and other heavy metals. Histamine acid phosphate, now used by subcutaneous injection to stimulate the secretion of hydrochloric acid for the fractional test meal, has been added. The maximum dose of cinchophen, of which the dangers have been again shown recently, is reduced to 10 grains (0.65 Gm.). The dose of iron and ammonium citrate is increased to from 20 to 40 grains (1.3 to 2.6 Gm.).

#### Increased Attention to Physical Education

The Board of Education, in fulfilment of the government's policy announced at the last general election, has sent a circular to the local education authorities dealing with the provision of suitable clothing and footwear for school children during games and other physical exercises. This circular is the last of four on physical education issued during the year by the board. The board is at present concentrating on the senior children between 11 and 14 or over. The new senior schools are well equipped for physical education, but improvement is needed in some of the older ones which have a playground but no playing

field or gymnasium. The more modern type of school has these. In 1921 a school for 1,000 children was thought to be well off with a site of  $1\frac{1}{2}$  acres; a new school for the same number now has 16 acres.

A well known educationist points out that every year thousands of graduates leave the universities, of whom 90 per cent would be better educated had their curriculum included physical education. He points out that where physical education is compulsory the students show educational as well as physical advantages compared with those for whom compulsion does not exist.

#### Message to Automobile Drivers

Mr. Hore-Belishs, the minister of transport, has written a personal message to drivers, which the local authorities are asked to issue when a license is renewed. He points out that last year there were 6,300 fatal accidents on our roads and that automobiles were involved in 5,700 of these. These accidents brought to death 6,500 people—nearly twenty a day. In most cases the driver's action was not criminal, but deaths were generally due directly or indirectly to an automobile. "If you will help in securing a higher standard of care we shall get at once a big reduction. Be prepared for the mistakes of others. Children cannot judge as well as grown-ups and they often forget the need for caution; their safety then depends on you. Nearly 900 children under the age of 11 were killed last year. Elderly people may be slow in hearing, thinking or moving; they must partly depend on you for safety. Nearly 1,500 persons over 60 were killed last year. Cyclists are apt to swerve; give them plenty of room. Nearly 1,400 pedal cyclists were killed last year. The most dangerous times are from 5 to 6 p. m. and from 10 to 11 p. m. The most dangerous day is Saturday; but please be cautious all the time. Most accidents occurred at times or places which are not themselves dangerous, on straight roads and in good light. It is not to blame one lot of persons or another that all these particulars of accidents are brought together, but for our guidance and yours."

### PARIS

(From Our Regular Correspondent)

Oct. 31, 1936.

#### Congress of Internal Medicine—Curable Meningitis

The twenty-fourth annual session of the French Congress of Internal Medicine was held at Paris October 12-14. The president for this session was Prof. Marcel Labbé. The two topics chosen for discussion were (1) acute curable forms of meningitis and (2) the parathyroid syndromes.

The first paper on acute curable forms of meningitis was on acute benign meningitis in adults and was read by Roch of Geneva, who first enumerated a large number of known or probable causes for the majority of cases. There exists also a smaller group (cryptogenic form) in which the etiology still remains obscure. Roch has observed thirteen cases belonging in the second group since 1923 and collected a number published by others. The acute curable form of meningitis, which Roch terms "benign lymphocytic meningitis," occurs predominantly in adults and adolescents. The onset is sudden, the appearance of prodromal symptoms being exceptional. The signs of a frank meningitis such as severe headache, Kernig sign, vomiting, and rarely constipation are the salient features. Symptoms of involvement of the optic and other cranial nerves, as well as absence of the Babinski reflex, are exceptional. Delirium is rarely noted and coma still less often. The headache is much less marked after lumbar puncture. Accompanying the symptoms of a meningitis are those of a generalized infection in the form of chills and fever of moderate degree. The duration of the disease varies from five to eight days, rarely longer. The cerebrospinal fluid is opalescent or clear and the majority of the cellular elements are lymphocytes

Cultures and animal inoculations are negative. The albumin content seldom exceeds 0.5 Gm. The globulin reaction is positive, whereas the chloride and dextrose percentage remains normal.

The clinical symptoms and results of laboratory studies enable one to exclude a tuberculous meningitis. As to the cause of this curable form of meningitis, one must consider hereditary predisposition, possibility of syphilitic or tuberculous infection, spirochetosis, previous anaphylactic manifestations, injury, insolation, mumps, herpes, focal infection and intestinal parasites. The acute benign lymphocytic form of meningitis is not related to poliomyelitis, as has been claimed. It is rather a meningeal form of epidemic encephalitis. This is shown by the fact that the majority of cases have been observed during the height of an encephalitis epidemic.

The second paper in the symposium on acute curable meningitis was by Lesné of Paris and Boquien of Nantes, entitled Curable Lymphocytic Meningitis in Children, which most commonly occurs between the ages of 5 and 12 years. The portal of entry is the nasopharynx and the clinical picture is quite typical. The onset, as a rule, is acute but it may be even hyperacute, which differentiates it from that of a tuberculous meningitis. The headache at the onset is extremely severe, mostly in the occipital region and accompanied by vomiting. Cases presenting prodromal symptoms are seldom seen. Examination of the child reveals marked signs of a meningitis, such as rigidity of the neck and the Kernig sign in its two forms. The tendon reflexes are normal in some cases and only a little exaggerated in others. The skin reflexes show slight change and one never finds a Babinski sign. Cutaneous hyperesthesia is striking, but vasomotor changes are less marked than in tuberculous meningitis. Photophobia is frequent and the fundus of the eye often presents a papillitis, edema of the papilla or stasis and at times even retinal hemorrhages. Some cases have been reported of paralysis of the ocular muscles. During the entire course, the temperature varies from 100 to 102 F. As a rule, the duration varies from two to four weeks. There are no evidences of stupor or coma. The main diagnostic feature is the result of the examination of the cerebrospinal fluid, which is clear but contains from 300 to 500 lymphocytes per cubic centimeter. This reaction decreases as the symptoms become more intense, thus differing in this respect from a tuberculous meningitis. The polymorphonuclears predominate at first and then the lymphocytes; hence the authors believe that it would be better to term the disease a "curable or benign serous meningitis." There is much less albumin content in the liquid than one would expect from the presence of so many leukocytes. Dextrose is normal and the chlorides are but little modified. With few exceptions the Wassermann reaction is negative but that of Dandy often positive. Bacteriologic examination is uniformly negative. Following lumbar puncture there is a remarkable recession of symptoms. There are typical cases in which the symptoms are as just described but with others (*formes frustes*) in which the diagnosis can be made only following the examination of the spinal fluid. Also "recurrent" cases have been observed which continue for months. The prognosis is favorable, sequelae being rarely seen. The differential diagnosis from a tuberculous meningitis is based on exposure to infection, prodromal period, "hostility" of the patient, signs of bulbar or basilar involvement, emaciation and stupor as being typical of a tuberculous meningitis. A negative skin and intradermoreaction also speaks against such causation. The higher albumin content of the spinal fluid and the finding of tubercle bacilli by stain, culture or inoculation make the differentiation an easy task. Up to now the etiology has been obscure, but recent studies make it seem probable that it is due to some form of virus. As to treatment, it is purely symptomatic.

In the discussion, Oelsnitz of Nice stated that the diagnosis was easy after several days of observation, but not at the onset. He believes that the changes in the dextrose content of the spinal fluid are of more value than those in the percentage of chlorides. In the curable lymphocytic form of meningitis the dextrose content is normal and, with few exceptions, remains so, whereas in a tuberculous meningitis the dextrose content constantly diminishes. Etienne Bernard emphasized the three salient features of a curable lymphocytic meningitis; viz. (1) the acute onset, (2) the intense (500-600) lymphocytic reaction in the spinal fluid and (3) negative skin reactions to tuberculin.

### The Medical Profession and the Department of Public Health

European France is divided into eighty-six departments or counties for purposes of administration. In each department there is a union or "syndicate" of physicians, which looks after the interests of its members, especially in the relations between the profession and the governmental agencies. The largest of these syndicates is that of the department of the Seine, in which Paris is situated. Every effort is being made by the medical profession all over France and its colonies to aid the government in its plan to improve the condition of the worker in accordance with the socialization plan introduced by the present ministry in June. The administrative council of the syndicate of physicians of the department of the Seine unanimously voted July 22 to offer its cooperation to the government by assuming responsibility for a program of prophylaxis of disease and protection of the health of the community. That such an offer will encounter many obstacles is evident in reading the discussion that took place before the resolution of cooperation was passed by the council of the syndicate. The plan of the latter is as follows:

A collective contract will be made between the government authorities and the profession to take charge of the socialized medicine program. This contract is to include:

1. The organization of social centers (one for each ward of Paris and one for each group of suburbs).
2. The organization of prophylaxis:
  - (a) In the private consultation offices of the practitioners.
  - (b) In public or private organizations already existing.

This problem of organization of prophylaxis includes antepartum and nursing clinics, periodic examination of children before and during school years, periodic examination of adults, and prophylaxis against tuberculosis, venereal diseases, mental diseases, variola, diphtheria, typhoid and cancer. For each of these special objectives, either the physician's private office or the existing bureaus will be organized so that the primary consideration will be to conserve the relation now existing between the family and the general practitioner so that the latter will not be deprived of his means of earning a living.

The social center will serve not only as an administrative center of coordination of social work but also as a bureau of information for those individuals who are covered by the social insurance law, a center of control and payment of premiums to the assured and a bureau of medicosocial statistics. No medical consultations will be given by these social centers. They will have as director a government official appointed by and responsible to the inspector of hygiene of the respective department. The social center head has under his control all the social assistants and hygiene officers of the department. A committee of coordination on which the local medical syndicate has a representative will meet at least once every three months to review the work of the social center.

A "maternity booklet" with detachable pages will be given to every pregnant woman. A minimum of three antepartum examinations must be recorded and the results sent either to the social insurance authorities in the case of those women

who are covered by this law or to the social center in the case of noninsured women. If the latter have consulted a private physician, they will be reimbursed for any medical fee by the social bureau.

Every citizen from birth to death ought to have recorded in a booklet the various ailments for which he has received medical attendance. No such law exists as yet for every one in France, although the keeping of such a book is made obligatory for children who are wards of the state. If this should be applied universally, the records of periodic examinations could be inscribed and be of great value as the child grows older.

Between the ages of 6 and 14 years, the examination of school children is well organized in the department of the Seine, but little attention is paid to those above this age in the public schools. Recently the question of obligatory periodic (every six months) examinations at health centers for all pupils above the age of 14 years has been discussed. The syndicate believes that every practitioner, no matter whether a school inspector or not, should be permitted to make such examinations. This would be of great value if every pupil had a "health book" (*livret de santé*) kept up since birth.

According to the social insurance law, periodic health examinations of adults are supposed to be made every five years, but, in spite of the frequent demands of organized medicine to carry out this provision of the law, the authorities have thus far refused to do so. The Medical Syndicate of the Seine believes that such periodic examinations can be made by the family physician with the aid, as the necessity arises, of specialists. For those unable to pay, the public clinics are always ready to help. All such periodic health examinations should be recorded in the health book, which is to remain in the possession of the applicant.

The present organizations in the department of the Seine are adequately equipped to fight tuberculosis, but there are still a number of individuals who hesitate to apply for examinations in the special dispensaries and hospital services. Antivenereal and mental disease prophylaxis is well organized. Vaccination against typhoid, variola and diphtheria is, as a rule, carried out by practitioners, but the council suggested that it would be advisable to have these recorded in the health book if the latter innovation is made obligatory.

#### PROPOSED PREVENTIVE MEDICINE ORGANIZATION

The objective of the control should be to maintain a close surveillance not only of the already existing organizations but also of the work of the general practitioner who is to aid in the proposed preventive medicine plan. This control should include:

1. An administrative control by the social centers of both the existing organizations and practitioners. The work of the latter ought to be chiefly diagnostic and not therapeutic.

2. Technical control by the syndicate or medical union (of the department of the Seine) of the prophylactic work carried out in the offices of the practitioners.

One of the principal objections to this plan of enlisting the profession in this preventive medicine work is that it will entail a vast outlay of money by the state and local governments. The syndicate, however, is of the opinion that the results obtained would justify this expense, and such a method of handling the problem would avoid the less welcome threatened assumption of the task of prophylaxis by the state with construction of many new buildings as state health centers and the creation of a horde of office holders. In addition, the general practitioner would be able to make a living, which is not an easy task at present in France. The plan would not deprive him of the privilege to treat patients. Only those physicians who are members of a syndicate or medical union will be permitted to participate in this collective contract with

the state to take charge of preventive medicine. The fee table will be arranged between the state and the syndicates.

In the discussion on the plan, the question was raised as to how it would be possible to limit the work of the social centers to prophylaxis and not invade the field of treatment. The opinion of many was that this would be impossible and thus, in the end, the general practitioner would be the sufferer, because in many diseases, such as tuberculosis or syphilis, the prophylaxis must inevitably be followed by treatment.

#### Investigation of the Divining Rod Problem

The National Health Bureau has published a report on the results of an investigation, carried on under its direction, of the whole question of divining rods and earth rays. This report constitutes a noteworthy answer to the many assertions that have been made with regard to these matters.

In November 1933 the National Health Bureau in a "warning against the purchase of screen apparatus, electric spark devices and the like" had taken a stand on the question of whether there exist (as the dousers insist) a type of rays noxious to health, the proof of which it is supposedly possible to establish by the aid of divining rods, certain physical apparatus serving as a substitute for such rods or by peculiar sensory reactions of individual persons. At that time the National Health Bureau mentioned how public health might be jeopardized through misleading propaganda having to do with this "Earth Ray Theory." It was then deemed necessary to launch a large scale offensive against this source of disturbance among the population.

The National Bureau of Health set about organizing various commissions composed of a large number of professional representatives of all interested branches of science together with several members of the "National League for Rhabdomantic Affairs"; that is, actual well known dousers. The inquiry was carried out with complete lack of bias. It was held to be particularly desirable that the participating dousers and inventors of dousing apparatus should be allowed every possible consideration compatible with the approved fundamentals of scientific research work.

The following working basis was established for this cooperative investigation: It has been asserted by many rhabdomancers that so-called earth rays emanate from springs of water and from certain subterranean geological surroundings, and further that the action of these rays on living organisms may be the cause of impaired health and even of distinct diseases. The virulence may also be influenced by the "earth rays." The most divergent opinions with regard to the nature of these forces are entertained by persons who profess to believe in their existence; now the explanation is based on electrical influences, now on magnetic influences or on radiations of a corpuscular nature. No proof of the validity of a single one of these various hypotheses has to date been adduced by the adherents of the "Earth Ray Theory."

A physical confirmation of the existence of "earth rays" has not been forthcoming despite the fact that scientific research on radiant energy has made such great advances in recent years. And most certain it is that within the entire realm of the electromagnetic wave spectrum, from the hardest gamma rays to the electric waves, there are present none but the physically recognized and studied categories of rays.

As proof of the existence of "earth rays" there are adduced on the part of the rhabdomancers their own subjective reactions, reactions that cannot be verified by objective criteria. A majority of these reactions may be explained on the basis of anticipatory or wishful ideas. Then, besides, there is the alleged

deflection of the divining rod, which is supposed to take place without any conscious or unconscious influence being exerted. But for this phenomenon too a scientifically authenticated demonstration has yet to be recorded.

Different varieties of physical apparatus are also supposed to serve for demonstrations of the "earth rays." The measuring principles of this apparatus are based on the most disparate concepts of the nature of the "radiation." And finally there are certain devices that appear absolutely senseless to the scientist and which are supposed to screen off the so-called earth ray; in other words, remove the noxious influence from human beings, animals and plants.

The commissions whose task it was to elucidate the whole matter of "earth rays" and divining rods had accordingly to seek answers to the following questions: 1. Is there such a thing as a specific demonstrable deflection of a divining rod? 2. Is there any relation whatever between the "earth ray zones" delineated by the dousers and the state of health of the men and animals living therein? Is the culture of bacteria influenced by these "earth rays"? 3. Is it possible to check the claims of the dousers by means of the physical apparatus which are supposed to possess the same virtues as the divining rod? 4. Provided "earth rays" exist, is there any contrivance by which they could be screened off?

The answers, formulated in the course of this inquiry, turned out to be altogether in the negative: 1. (a) The observations of several approved dousers on "earth ray zones" (so-called irritant zones) in the same general region failed to exhibit any correspondence. (b) The data on "earth ray zones" of a certain region supplied by individual dousers were not consistent on repetition of the tests. 2. (a) The observations of various dousers on the alleged cancer-producing earth emanations present in dwellings fail to demonstrate any correlation whatever between the alleged "irritant striae" and the incidence of actual statistically recorded cases of cancer. As for the so-called cancer houses, which, according to the dousers, are supposed to present peculiar dangers for persons dwelling in them, proof of their existence is utterly lacking. (b) Furthermore, no pathogenic influence on animals of the hypothetical "earth ray" could be detected by means of the divining rod. "Irritant striae" were detected in the stables of healthy live stock quite as frequently as in the quarters of less healthy beasts. (c) In animal experimentation with the most diverse agents of infection, no influence on the virulence was observable that could be attributed to "earth rays." 3. The apparatus (termed "objective divining rods") suitable for demonstrating the existence of "earth rays," so far as they were inspected by us, were found to be completely useless, the claims of the manufacturers notwithstanding. 4. Since, therefore, no proof has been advanced that confirms the existence of a pathogenic radiation supposedly detectable by the aid of a divining rod or equivalent apparatus, any question of screening off the "rays" is altogether meaningless. Moreover, no screening device examined by us and put to the test by various dousers showed any demonstrable influence whatever, either on the divining rod or on the indicators of the instruments. 5. Finally, the claim that the divining rod is able to detect foci of disease in men and animals was examined. No corroborative evidence was forthcoming. There was no difference manifested between the deflections of the rod in the presence of healthy or of sick animals.

The dangers to public health as described in the observations of the dousers cannot, according to the National Bureau of Health, as yet be demonstrated by any evidence worthy of belief. Nor has the investigation sponsored by the bureau been able to bring to light the slightest proof of the actual existence of alleged "earth rays" pathogenic in nature and particularly likely to cause cancer. Assertions to the contrary current in certain circles are to be regarded as the outgrowth of irrational popular apprehensions.

### Water Supplies in the Netherlands Indies

The journal *Water* has recently published some interesting data on water supplies in the Netherlands Indies. Three types of supply are distinguished, according to origin: spring water, underground water and surface (river) water. Spring water requires the minimal treatment. Towns that receive their water from springs are generally located in the mountains; for example, Bandoeng, Malang, Soekaboemi, Buitenzorg, Magelang and Tandjoer, all in Java, Fort de Koek and Padang Sidempoean in Sumatra and Den Paser-Tabanan on Bali. Certain communities not far distant from the mountains also receive spring water: Semarang, Djokja, Tegal, Solo, Pasoeroean and Medan. In addition, the importance of the cities of Batavia and Surabaya justifies the use of spring water, which is transported to these places at great expense. The waters of the seven springs that serve Bandoeng vary in composition. The water from three of these springs is hard and it also requires aeration. The waters of two other springs are moderately hard and are aerated and filtered through marble. Waters of the two remaining springs are soft and are also filtered through marble.

As for the underground waters, if they are not located at too great a depth (as at Madioen and Kediri) they are pumped up to high reservoirs and deacidified by aeration. In other places the water is procured from artesian wells. A part of Bandoeng's water supply is of artesian origin and has caused no end of trouble, owing to deposits of manganese in the pipe lines. Installation of an experimental plant for aeration and for filtration through coarse sand did not at first produce favorable results, but at the end of a year enough pyrolusite had been deposited on the sand to allow catalytic oxidation of the manganese compounds.

The river waters differ from those of Europe. They are yellowish brown, seldom transparent and often extremely turbid. The powerful influence of insolation and the rapidity of the current are factors that contribute to a good biologic purification, but the pollution of the river banks is such that bacteriologic conditions are no better than those of the European surface waters. In high valleys, at Banka for example, slow filtration through sand may be successfully practiced. At Benkoelen the water is soft and so deficient in carbon dioxide that the addition of lime is inoperative and it is necessary actually to add carbon dioxide. At the same time the attempt is made to obtain coagulation in an alkaline medium. The use of sodium bicarbonate makes possible the deposit of a layer of calcium carbonate, which serves as a protection to the conduits. At Samarinda the presence of humic acid is combated by coagulation with aluminum sulfate.

The water is everywhere sterilized with chlorine, but owing to the heightened temperature of the water, chlorine may disappear rapidly and a new multiplication of bacteria take place. Chloramine, although less effective than free chlorine, represents an improvement over the latter, since it is retained in the water for a longer period.

### The Fight on Ancylostomiasis

Dr. Josephus, speaking at the International Bureau of Public Hygiene, described the campaign against ancylostomiasis and the truly marvelous result obtained; namely, the complete disappearance of the disease in question.

In 1906 a carefully planned body of legislation for the operation of mines was established by royal decree. One section of these statutes dealt wholly with antiancylostomiasis measures: it provided for the medical examination of all miners and stipulated how frequently such examination should take place and the routine to be followed. Furthermore, the law prohibited

the hiring of any miner who was an ascertained carrier of *Ancylostoma* in the form of the worm, the eggs or the larvae. Specific clauses also governed the construction of lavatories, water closets and so on at the surface of a mine as well as the use of receptacles for excreta below ground. The latter were to be emptied and cleaned only at the surface and never within the mine proper.

This antiancylostomiasis legislation of 1906 remained in force until 1925. By that time it was conceded that the disease had disappeared and the danger no longer existed. There remained only an insignificant number of carriers of eggs or larvae and these persons could be easily detected by the medical service without recourse to any special measures.

Although no longer impelled so to do by legal obligations, the medical service of the miners remains sedulous and continues its observations. The service is so organized that no diseased or suspected person can escape supervision and examination.

Under date of March 1936 Dr. Vossenaar, superintendent of medical service in the mines, writes approximately as follows: "In 1930 an examination of 4,997 specimens from those miners who were deemed to have been most exposed to infestation took place under my direction. Among these miners there were discovered two carriers of worms or of larvae. These two men, foreigners both, were not ill and treatment was successfully administered. For various reasons, research activity in this sphere has ceased but the organized medical service is still entrusted with the detection of such cases as in the course of time may present themselves. Moreover, foreign miners are no longer hired. This report, although of the briefest, is none the less revealing as it demonstrates above all how, by the application of prophylactic measures and sanitary precautions, the danger of ancylostomiasis in mines may be eliminated. The general condition of the mines throughout the Netherlands is excellent: the most rigorous cleanliness possible prevails, the ventilation is more than sufficient, dampness is lacking and the underground temperature is never too high."

## Marriages

HOBART McVICKER AGNEW, Montclair, N. J., to Miss Alice P. Himmelsbach of New York, October 10.

JOSEPH SLOAN BELL to Miss Elizabeth Webb Russell, both of Hoopeston, Ill., in Chicago, December 3.

FLORENCE ELIZABETH AHLFELDT to Mr. Samuel Parke Rogers, both of Philadelphia, October 24.

EDWARD VALENTINE SEXTON, Teaneck, N. J., to Miss Anna Mary Murphy of Jersey City, recently.

MYRON B. ALLEN, Hoschton, Ga., to Miss Ruth Lott of Braselton, at Walhalla, S. C., recently.

WILLIAM T. SHELL JR., Corsicana, Texas, to Emma Jean Smith Lock of Mexia, October 14.

ALTUS B. HARVEY to Mrs. Inez Sylverstein Whittle, both of Tylertown, Miss., November 7.

RONALD F. MARTIN to Miss Mary Ellen McLaughlin, both of Sioux City, Iowa, October 15.

RUDOLPH ANGELL to Miss Irma Marilyn Goldstein, both of Rochester, N. Y., August 31.

ABRAHAM M. SCHAEFER to Miss Alice Leavitt, both of Hartford, Conn., September 27.

ABRAHAM ZLOTNICK to Miss Jeanne Gruberman, both of New York, November 26.

THOMAS F. AHEARN JR., Chicago, to Miss Mary Doolin of Hammond, Ind., recently.

CRAIG D. ELLYSON, Waterloo, Iowa, to Miss Johanne Wilkens of Chicago, October 26.

HARRY S. GOOD, Womelsdorf, Pa., to Miss Julia O'Dell of Pottstown, October 1.

CLAUS H. ROBOHM to DR. DOROTHY MARIE BAUER, both of Brooklyn, October 9.

PETER A. ROSI to Miss Gina Vanna, both of Chicago, recently.

## Deaths

Willis Fastnacht Manges ☉ Philadelphia; Jefferson Medical College of Philadelphia, 1903; chairman of the Session on Radiology in the Section on Miscellaneous Topics of the American Medical Association, 1923-1924; professor of roentgenology at his alma mater; served during the World War; fellow of the American College of Physicians; member, secretary, 1914-1916, president in 1918, and chairman of the executive council in 1924 and 1930, of the American Roentgen Ray Society and member of the American College of Radiology; formerly on the staffs of the Philadelphia General Hospital and chief roentgenologist to the Bryn Mawr (Pa.) Hospital; aged 59; was awarded an honorary doctor of science by Gettysburg College in 1928; on the staff of the Jefferson Medical College Hospital, where he died, November 24, of coronary occlusion.

Edward Reynolds, Boston; Harvard University Medical School, Boston, 1885; chairman of the Section on Obstetrics, Gynecology and Abdominal Surgery of the American Medical Association, 1915-1916, and member of the House of Delegates in 1921; member of the Massachusetts Medical Society; fellow of the American College of Surgeons; at one time vice president and chairman of the board of directors of the American Society for the Control of Cancer; past president of the American Gynecological Society; formerly on the staffs of the Massachusetts General Hospital, Boston Lying-in Hospital and the Boston City Hospital, at one time director of the Peabody Museum of Archaeology and Ethnology of Harvard University; aged 76; died, October 16.

Thomas Craig Redfern ☉ Winston-Salem, N. C.; Long Island College Hospital, Brooklyn, 1916; served during the World War; fellow of the American College of Physicians; past president and secretary of the Forsyth County Medical Society; formerly councilor of the eighth district of the Medical Society of the State of North Carolina; associate on medical service, City Memorial and North Carolina Baptist hospitals; member of the board of governors of the Forsyth County Tuberculosis Sanatorium; aged 44; died, October 16, of coronary thrombosis.

Robert J. Gibson ☉ Lieut. Col., U. S. Army, retired, New Haven, Conn.; Yale University School of Medicine, New Haven, 1879; entered the regular army as an assistant surgeon in 1880; appointed a captain in 1885; was made a major in the M. C., U. S. Army, in 1898; retired with rank of lieutenant colonel in 1910 for disability in line of duty; veteran of the Spanish-American and Indian wars; aged 81; died, October 9, of cystitis and uremia.

Owen Joseph Mink ☉ Medical Director, Captain, U. S. Navy, Washington, D. C.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1904; fellow of the American College of Surgeons and the American College of Physicians; entered the navy in 1904; assistant to the chief of the bureau of medicine and surgery of the navy department; aged 57; died, October 21, in Chevy Chase, Md., of coronary thrombosis.

William Alfred Mann Sr. ☉ Chicago; Chicago Medical College, 1883; assistant clinical professor of ophthalmology and otolaryngology at his alma mater, 1903 to 1906; past president of the Evanston branch of the Chicago Medical Society; oculist and aurist to the Michael Reese Hospital dispensary, 1890-1899, and the Provident Hospital, 1899-1910; aged 77; died, October 8, at his home in Wilmette, Ill., of carcinoma of the colon.

David Yandell Roberts, Louisville, Ky.; University of Louisville Medical Department, 1900; member of the Kentucky State Medical Association; surgeon to the SS. Mary and Elizabeth Hospital; district chief surgeon, Louisville and Nashville Railroad Company; district surgeon, Pullman and Western Union Telegraph companies; aged 57; died, October 12, of heart disease.

Max Greenwald, New York; Baltimore Medical College, 1907; member of the Medical Society of the State of New York; clinical instructor in medicine at the New York Medical College and Flower Hospital; served during the World War; on the staff of the Metropolitan and the Beth David hospitals; aged 49; died, October 2, of coronary thrombosis and arteriosclerosis.

Norman James Pike, Saginaw, Mich.; Michigan College of Medicine and Surgery, Detroit, 1891; Queen's University Faculty of Medicine, Kingston, Ont., Canada, 1898; member of the Michigan State Medical Society; served during the World War; aged 71; died suddenly, October 9, of duodenal ulcer, cerebral hemorrhage and heart disease.

**Samuel P. Glover** \* Altoona, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1884; veteran of the Spanish-American War; member of the American Academy of Ophthalmology and Oto-Laryngology; on the staff of the Altoona Hospital; aged 76; died suddenly, October 3, of coronary occlusion and diabetes mellitus.

**Eugene D. Regan**, Milwaukee; Milwaukee Medical College, 1898; member of the State Medical Society of Wisconsin; formerly assistant clinical professor of ophthalmology at the Marquette University School of Medicine; member of the State Medical Society of Wisconsin; aged 62; died suddenly, October 15, of coronary occlusion.

**Arthur H. Reading**, Lake Worth, Fla.; Bennett College of Eclectic Medicine and Surgery, Chicago, 1886; at one time professor of physical diagnosis at his alma mater; formerly on the staffs of the Cook County and the Francis E. Willard hospitals, Chicago; aged 73; died, October 1, of endocarditis.

**Jesse Addison Sprowls** \* Donora, Pa.; Western Pennsylvania Medical College, Pittsburgh, 1896; formerly member of the state legislature; at one time member of the board of health and board of education of Donora; for many years bank president; aged 65; died suddenly, October 10, of coronary occlusion.

**Charles Schott** \* Chicago; Rush Medical College, Chicago, 1909; member of the American Academy of Pediatrics; served during the World War; on the staffs of the Illinois Masonic Hospital, St. Joseph's Hospital and the Children's Memorial Hospital; aged 51; died, October 1, of heart disease.

**I. Herbert Tobias**, Hancock, Md.; Ohio Medical University, Columbus, 1903; member of the Medical and Surgical Faculty of Maryland; aged 62; formerly on the staff of the Washington County Hospital, Hagerstown, where he died, October 2, of angina pectoris and multiple sclerosis.

**Finis Coleman Little** \* East St. Louis, Ill.; St. Louis University School of Medicine, 1906; during the World War served on a draft board; formerly member of the board of fire and police commissioners; aged 64; died, October 13, in the Christian Welfare Hospital, of arteriosclerosis.

**George Ernest Poor**, Medfield, Mass.; College of Physicians and Surgeons, Boston, 1904; member of the American Psychiatric Association and the New England Society of Psychiatry; formerly on the staff of the Medfield State Hospital; aged 61; died, October 29, in Framingham.

**William Henry MacKay**, Washington, D. C.; Tufts College Medical School, Boston, 1914; served during the World War; for many years connected with the Veterans Administration Facility; aged 45; died, October 14, in Oteen, N. C., of pulmonary tuberculosis.

**Berry Hayden Smith**, Blythe, Ga.; Georgia College of Eclectic Medicine and Surgery, Atlanta, 1912; member of the Medical Association of Georgia; aged 54; died, September 27, in the University Hospital, Augusta, of injuries received in an automobile accident.

**David Simon Fleischhauer** \* Wabasha, Minn.; Cornell University Medical College, New York, 1899; past president of the Wabasha County Medical Society; formerly mayor of Wabasha; served during the World War; aged 59; died, October 14, of pneumonia.

**Harry Alexander Turk** \* East Liverpool, Ohio; Baltimore Medical College, 1907; served during the World War; formerly postmaster at Newell, W. Va.; aged 53; on the staff of the East Liverpool City Hospital, where he died, October 21, of cerebral hemorrhage.

**Hugh Martin Hall** \* New Carlisle, Ind.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1898; aged 64; died, October 18, in St. Bernard's Hospital, Chicago, of pneumonia, following an operation for hernia.

**Ernest E. Palmer** \* Kerrville, Texas (registered by Texas State Board of Medical Examiners, under the Act of 1907); past president of the Kerr County Medical Society; aged 80; died, October 14, in Sabinal, of injuries received in an automobile accident.

**James Rocquet Daboval** \* New Orleans; St. Louis University School of Medicine, 1925; professor of histology and pathology at Loyola University; aged 34; member of the staff of the Mercy Hospital, where he died, October 6, of cerebral hemorrhage.

**William G. Young**, Shepherd, Mich.; Saginaw (Mich.) Valley Medical College, 1903; member of the Michigan State Medical Society; aged 64; died, October 14, in the Carney-Wilcox Hospital, Alma, of injuries received in an automobile accident.

**Cyrenius James Newcomb** \* Bellefonte, Pa.; Western Pennsylvania Medical College, Pittsburgh, 1896; formerly a druggist; at one time physician to the State Penitentiary; aged 70; died, October 13, in the Presbyterian Hospital, of ulcerative colitis.

**Robert Emmet Hickey**, Milwaukee; Milwaukee Medical College, 1910; superintendent of the division of contagious diseases of the city health department; aged 50; died, October 8, in St. Mary's Hospital, of hemorrhage due to duodenal ulcer.

“THE RÔLE OF ALCOHOL IN CIRRHOSIS OF THE LIVER”

To the Editor:—I have read with interest the article in your October 10 issue entitled “The Rôle of Alcohol in Cirrhosis of the Liver,” by Drs. Boles and Clark. I realize that the reader may misinterpret. I realize further that histories of alcoholism and of previous acute infectious diseases are fallible. Nevertheless it is permissible to compare groups giving such a history with those that do not and, within limitations, draw conclusions. The authors have drawn such conclusions, but I submit that, particularly with reference to a history of alcoholism, the authors have drawn conclusions contrary to their data. It is stated that 228 of 4,000 patients gave a history of alcoholism. I infer that 3,772 patients gave no such history. Of the 4,000 patients, 243 subsequently gave necropsy evidence of liver cirrhosis. Of these 243 cases, eighty-four were from among patients who gave a history of alcoholism and 159 were from among the patients who gave no such history. Similarly, of 151 cases exhibiting livers weighing 2,000 Gm. or more, seventy-five were from among patients who had given a history of alcoholism. From these data one may construct the following tables:

TABLE 1.—Persons Giving a History of Alcoholism

Autopsies	Cases of Cirrhosis		Liver Weighing 2,000 Gm. or More	
	No.	per Cent	No.	per Cent
228	84	37	75	33

TABLE 2.—Persons Not Giving a History of Alcoholism

Autopsies	Cases of Cirrhosis		Liver Weighing 2,000 Gm. or More	
	No.	per Cent	No.	per Cent
3,772	159	4.2	76	2.0*

\* Apparently this figure is very slightly low, as it is stated that persons having leukemia and similar conditions were not included. One might, however, assume that the 33 per cent would be likewise affected.

Thus it would appear that in the population discussed by the authors a patient who gave a history of alcoholism was nine times as likely to exhibit cirrhosis of the liver as a patient who failed to give such a history, and that the patient with an alcoholic history was sixteen times as likely to show a liver weighing 2,000 Gm. or more. Hence the data presented do show a strong and significant association between a history of alcoholism and a subsequent finding of liver cirrhosis or enlargement and the authors draw the opposite conclusion! I believe it unfortunate that so large a material should be permitted to convey an interpretation contrary to its apparent evaluation.

HOLLIS S. INGRAHAM, M.D., Albany, N. Y.

[NOTE.—The letter was referred to Dr. Boles, who replies:]

To the Editor:—As our paper stated, Dr. Clark and I reviewed 4,000 autopsies and based our conclusions purely on positive evidence. We did not accept a clinical diagnosis of cirrhosis unless it was confirmed by microscopic examination of sections of the liver. The clinical histories of such cases were examined and with few exceptions it was noted that in all the cases clinically diagnosed as cirrhosis a special effort had been made to elicit an accurate history concerning the use of alcohol. In many instances the original history contained no reference to alcohol but on subsequent interrogation a positive history was obtained. Only cases with definite histologic

evidence of cirrhosis and a definite history, positive or negative, for alcoholism were therefore used in calculating percentages and drawing our conclusions.

Dr. Ingraham assumes that, because only 228 patients admitted the use of alcohol, 3,772 did not use it, which is in accordance with our figures. With equal propriety, however, we might have assumed that the same individuals, less 159 who persistently denied the use of alcohol on repeated questioning, were alcoholic. As a matter of fact, a certain number of them must have been alcoholic, for it is inconceivable that there would be an incidence of only 5 per cent (228/4,000) of alcoholism in the population of a large general hospital accepting only charity patients from a stratum of society known for its alcoholic proclivities. In the negative group of 3,772 cases we admit the probability of inaccuracy in a history concerning alcoholism and because of this did not consider them in estimating percentages. It was apparent that no special effort to elicit such a history had been made, as was done in the cases of cirrhosis about which we were mainly concerned.

RUSSELL S. BOLES, M.D., Philadelphia.

INSOLUBLE BISMUTH COMPOUNDS IN ANTISYPHILITIC TREATMENT

To the Editor:—The advisability of using insoluble bismuth compounds in antisyphilitic treatment is periodically brought up for discussion by medical societies, clinics and individual physicians. A general interest in this matter may justify a summary of my views, which have been given on occasion extemporaneously. My views are based on the results of experimental and clinical studies over a period of years of several bismuth compounds in our department and in the literature. The very extensive data of the literature, including most of ours, may be found in a recent compilation by Forst of Munich, probably the most complete and best, single, up-to-date summary of the pharmacologic and clinical actions of bismuth (*Handb. d. exper. Pharmacol.* 3:2249-2730 [part 4] 1935):

The use of insoluble bismuth compounds in antisyphilitic treatment has been considerably favored, although this usage represents a curious contradiction in pharmacologic principles. The inconsistency is impressive when this usage is compared with the practice of using only the soluble arsenicals. Why insolubility and unabsorbability should endow bismuth with desirable attributes in antisyphilitic treatment has been puzzling. Those who advocate insoluble bismuth do not advocate insoluble arsenicals; not even methods less spectacular than intravenous injection.

General experience now indicates that the same principles which apply to arsenicals also hold for bismuth, and, if high antisyphilitic efficiency is to be achieved, the soluble compounds of bismuth should be used, and not the insoluble. The facts as to poor body-availability of bismuth from insoluble compounds injected intramuscularly have been extensively ascertained by carefully controlled studies in both animals and man. For instance, the results with bismuth salicylate show that it is poorly, irregularly and incompletely absorbed. Only from 0.5 to not more than 10 per cent of the total bismuth injected is absorbed in two weeks, as compared with 50 per cent when soluble compounds are used. The remainder of this insoluble bismuth compound is encapsulated and remains localized in the muscles for weeks, months or years, a fact shown repeatedly by x-ray examinations. The plasma-bismuth after the bismuth salicylate amounts to only one-thirtieth to one-third that after the use of soluble compounds, despite a dosage from five to fifteen times greater. Other body fluids and tissues also contain less bismuth.

The intramuscular bismuth-depot is a continued source of danger for the patient. The capsule may break down as the result of various physiologic changes, such as the actions of

salts, water, exercise and fever. These agencies mobilize bismuth, increase its systemic action and frequently result in sudden bismuth poisoning. The mobilization of the metal is not self regulating so as to produce only the supposed advantages of a continued antisyphilitic action without any disadvantages. This is evident from the fact that the muscles contain a wholly uncontrolled depot of potential poison, which in the nature of things tends to be increased, if anything. These considerations point to the undesirability of bismuth salicylate as a choice compound in antisyphilitic treatment. Yet its use is advocated in many clinics and is followed parrot fashion by many practicing physicians. The comparative freedom from local irritation for the patient is presumably the main reason for using this insoluble compound; a slow and incomplete systemic action could hardly be an adequate reason. The circulating bismuth is obviously too small and irregular to do much good, and it cannot be materially increased by raising the dosage without increasing the hazard to the patient. Yet it is a demonstrated fact that antisyphilitic efficiency is directly proportional to the blood and tissue concentrations of bismuth. It seems clear that the use of insoluble bismuth compounds is not based on accepted scientific principles.

The practice of using insoluble bismuth compounds sheds a light on the skepticism of certain syphilologists, who discredit the value of bismuth in antisyphilitic treatment. This attitude has puzzled many investigators. Apparently, these skeptics have failed to test their impressions by a carefully considered use of soluble bismuth compounds, which are quantitatively absorbed, distributed and highly active. The greater therapeutic efficiency and usefulness of the soluble bismuth compounds is unquestioned, as is the case with the soluble arsenicals. Only when results are obtained under the most favorable conditions, in accordance with acceptable scientific criteria, will the full value of bismuth in antisyphilitic treatment be determined. Until then the position of the skeptics will remain untenable and unsound.

It is not amiss to point out in this connection that the French, who have been the most enthusiastic advocates of bismuth, have used almost invariably the soluble compounds, whereas the Germans and Americans, who have been less enthusiastic or more skeptical, have tended to use the insoluble. It is probable that there is more than a chance correlation between such clinical favoritism and skepticism and the physical and chemical properties and systemic actions of bismuth compounds, which determine the body availability and therefore the actions and usefulness of bismuth in the treatment of syphilis. For these various reasons the use of insoluble compounds of bismuth is, in my opinion, unwise and ill advised.

The uniformly high therapeutic rating accorded bismuth as an antisyphilitic remedy, when properly used, deserves more than skepticism engendered by use of compounds that cannot produce dependable and satisfactory results. Empiricism or arbitrariness in antisyphilitic therapy is not justified in place of the well planned and carefully controlled clinical experiment for confirmation or refutation of the generally much more satisfactorily obtained pharmacologic data. And if any field in medicine today is worthy of the most critical and rigid therapeutic experimentation, it is that of syphilis. Considerable progress in antisyphilitic therapy shall have been made when oral compounds are available that will enable a physician to maintain a patient on a long and intensive treatment without discouragement. Some preliminary skirmishes with bismuth in this direction indicate possibilities which further experimentation may settle favorably, something much to be desired for promoting the control and complete cure of syphilis.

P. J. HANZLIK, M.D., San Francisco.

Professor of Pharmacology, Stanford.  
University School of Medicine.

## Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

### TREATMENT OF SYPHILIS

To the Editor:—A woman, aged 28, weighing 88 pounds (40 Kg. 5 feet 3 inches (160 cm.) in height, married, a secundipara, consulted me Oct. 20, 1935. Three weeks previously her husband had begun treatment for primary syphilis. There was a history of exposure, an examination showed mucous lesions of the vulva. Treatment was begun and carried out as shown in the accompanying table. Neosarsphenamine was discontinued November 29, following the second nitritoid crisis. In view of the fact that later she noted some distress when near her husband on days he received neosarsphenamine, no further use of the drug has been attempted. She shows no reaction to injections of silver arsphenamine but, because of a possibility of argyria, mapharsen was attempted, fair severe nausea and vomiting following the last two injections. What treatment is advisable in view of the fact that pregnancy has occurred during this course of treatment, dating from February 2, the last menstrual period. Please omit name and address.

M.D., North Carolina.

### Course of Treatment

10/20/35	.....	Wassermann reaction +4	
10/22/35	Neosarsphenamine 0.6 Gm. bismuth 2		
10/26/35	Neosarsphenamine 0.6 Gm. bismuth 2		
10/31/35	Neosarsphenamine 0.6 Gm. bismuth 2		
11/ 7/35	Neosarsphenamine 0.6 Gm. bismuth 2		
11/14/35	Neosarsphenamine 0.6 Gm.	Wassermann reaction +2, Meinicke turbidity test +4	Nitritoid crisis
11/21/35	Neosarsphenamine 0.6 Gm.	.....	Nitritoid crisis
11/29/35	Neosarsphenamine 0.2 Gm. bismuth 2		
12/ 7/35	Bismuth 2		
12/14/35	Bismuth 2		
12/21/35	Bismuth 2		
12/28/35	Bismuth 2		
1/ 4/36	Silver arsphenamine 0.15 Gm.	Wassermann reaction negative	
1/11/36	Silver arsphenamine 0.15 Gm.		
1/18/36	Silver arsphenamine 0.3 Gm.		
1/25/36	Silver arsphenamine 0.3 Gm.		
2/ 1/36	Silver arsphenamine 0.3 Gm.		
2/ 8/36	Silver arsphenamine 0.15 Gm. bismuth 2		
2/15/36	Bismuth 2		
2/21/36	Bismuth 2		
2/28/36	Bismuth 2		
3/ 6/36	Bismuth 2		
3/13/36	Silver arsphenamine 0.15 Gm. bismuth 2	Wassermann reaction negative, Meinicke negative	Pregnant
3/20/36	Silver arsphenamine 0.3 Gm.		
3/28/36	Silver arsphenamine 0.16 Gm.		
4/ 3/36	Mapharsen 0.04 Gm.		
4/10/36	Mapharsen 0.04 Gm.	Nausea and vomiting	
4/17/36	Mapharsen 0.04 Gm.	Nausea and vomiting	

ANSWER.—In view of the fact that this patient with early syphilis of approximately eight months' duration is now pregnant, it is doubly urgent to attempt the continuation of treatment with some one of the arsphenamines. This is necessary not only for the adequate treatment of the patient's own infection but for the protection of the fetus. Since she shows no reaction to silver arsphenamine, treatment with this drug should be continued in alternation, as before, with the bismuth compound. Since the patient weighs only 88 pounds, a dose of 0.2 Gm. of silver arsphenamine may be considered adequate. There is no danger of argyria until approximately thirty such injections have been given, which, considering the patient's serologic progress, should be amply sufficient to complete her treatment. It is suggested that the courses of silver arsphenamine be of eight injections each, separated by courses of bismuth compound of from six to eight injections each, the treatment being timed if possible so that at least three to four injections of silver arsphenamine are given just prior to delivery. The patient's spinal fluid should be examined but, in view of her pregnancy, this may be postponed until immediately after delivery, when a routine lumbar puncture should be carried out while the patient is still in bed. The continuous plan

of treatment which has so far been used is correct and should be followed in the same manner, regardless of pregnancy.

The patient should be encouraged to tolerate minor treatment reactions in view of the importance of securing a healthy child.

### MYOCARDITIS

*To the Editor:*—A patient developed myocarditis following a cold. Her blood pressure remains low and her pulse rate rapid. She is obese, weighing 227 pounds (103 Kg.). She was kept in bed for six weeks, the weakness disappearing, but on getting up and doing her work she becomes very tired and has attacks of palpitation. She and her husband operate a greenhouse, and it is almost a necessity for her to work. She has been given a heart tablet of digitalis with hyoscyamus, and also strychnine. She has also lost weight moderately. For weakness she has also been given whisky two or three times a day in moderate doses. I have been reducing her weight by a diet, but with very poor results. Could you suggest a method of diet to help and also suggest how to strengthen the heart action and how to overcome her weakness? She has been taking liver and iron (Lextron) to combat slight secondary anemia. Do longitudinal ridges of the finger nails have any bearing on her condition? This condition with brittleness has developed only since her recent illness. Please omit name.

M.D., Ohio.

*ANSWER:*—A number of points need further study before an accurate appraisal of this case may be made. "Chronic myocarditis" following a cold usually means the aggravation of a preexisting cardiac degeneration. The presence of weakness, rapid heart rate and hypotension does not necessarily mean that the patient has myocarditis. It is assumed that there is no cardiac enlargement and that there are no signs of cardiac insufficiency such as edema, dyspnea and similar phenomena. The obesity, which yields so poorly to diet, would suggest a metabolic disorder. This suspicion is strengthened by the occurrence of the brittle finger nails with ridging. A hypothyroidism is often accompanied by these symptoms and in addition one often finds dry skin and hair, together with weakness. A thyroid disorder is frequently aggravated by the occurrence of an acute infection. A study of the metabolic rate in this patient would be of value.

Dietetic treatment to overcome the weakness and strengthen the heart does not offer much prospect of success. An under-nutrition diet to combat obesity is not likely to offer aid to a weakened heart. The remaining underlying factors must be worked out. Digitalis is not likely to be helpful unless cardiac decompensation exists. The iron content of the liver and iron mixtures is not great enough to do much real good in secondary anemia.

If this patient has undoubted cardiac degeneration or has suffered some acute coronary damage further rest must be insisted on in spite of the necessities of work, but from the facts given such a diagnosis seems open to argument. It must be remembered that in the presence of a constitutional or metabolic disorder a slow recovery is not unusual.

### CYSTITIS AND PREGNANCY

*To the Editor:*—A patient, now aged 29, had a two months pregnancy interrupted in 1932 because of an acute colon bacillus cystitis. There was no evidence of kidney infection, and the acute manifestations of the cystitis subsided rapidly; but some increased frequency, urgency, burning and tenesmus have persisted, gradually improving, so that for the last year she has had only mild and transient symptoms of this kind during some of the menstrual periods. At the present time the urine is normal and she is in good general health. Please give me an opinion, should pregnancy again take place, as to the likelihood of cystitis again occurring, and the possibility of the kidneys becoming involved, and suggest prophylactic measures against urinary infection. Please omit name.

M.D., Kentucky.

*ANSWER:*—In view of the fact that this patient has fully recovered from a cystitis which she had nearly four years ago, it seems unlikely that she would have a recurrence. As there has never been any evidence of a pyelitis, she would not be more likely to develop such an infection than any other pregnant woman. It also seems that in the absence of complications other than cystitis, the therapeutic abortion was hardly justifiable.

The urine should be examined bacteriologically to determine whether or not she is still harboring pathogenic organisms. If so, they should be eliminated by proper treatment before pregnancy occurs.

There is no specific therapy for such an infection of the urinary tract, but, in general, the bladder should be emptied promptly when the desire to micturate occurs, so that the wall does not become unduly stretched from retention. The position of the uterus should be checked and any malposition corrected. Elimination should be properly maintained from the gastro-

intestinal tract, and plenty of fluid should be imbibed so that the urinary tract is continually flushed. The resistance of the patient should be maintained by proper hygiene with adequate sleep, recreation and exercise. Frequent changes of posture would be desirable, making use of the knee-chest and the Sims' position, and possibly using the monkey-walk.

Colon bacillus cystitis is not usually recognized as an indication for therapeutic abortion, and pyelitis is a relatively frequent complication of pregnancy but is an infrequent indication for its termination. It would seem justifiable to allow this patient to become pregnant again, and the probability is that she would go to term without serious difficulty.

### INTRAPLEURAL PRESSURE DURING ARTIFICIAL PNEUMOTHORAX

*To the Editor:*—In *Queries and Minor Notes* in *THE JOURNAL*, April 4, you state that during forcible inspiration there is greater negativity of intrapleural pressure if the glottis is open rather than closed. I believe you are mistaken in that statement. Intrapleural pressure with expiration attempted, glottis closed, will read as high as 120 cm. of water; inspiration attempted, glottis closed, will read as low as —75 cm. of water. Almost all pathologic conditions of the lung and pleura make a quite noticeable difference in intrapleural pressures and not as you state "would not vary much from the normal, healthy pleural cavity." These changes are due to lung and pleura altered elasticity, atelectatic processes, adhesions, and so on.

H: W. GRANZEAU, M.D., Burlington, Wis.

*ANSWER:*—In the ordinary practical work of treatment by pneumothorax, the excessive respiratory gymnastics are not only not necessary but dangerous on the first induction of therapeutic pneumothorax and dangerous in the liability to traumatize the lung. On trying forcible inspiration with the glottis closed, with a specially constructed manometer to avoid aspiration, the negativity was found to be greater, as shown in this table of twelve patients who had a pneumothorax.

In the closing statement that pressure would not vary much from normal in the case of pathologic conditions, the answer stated the writer's experience of the manometric readings on the first entry into the pleural cavity of tuberculous patients who came for treatment. First readings, before injection of

### Results of Normal Inspiration, Forcible Inspiration, and Forcible Inspiration with the Glottis Closed

	Normal Inspira- tion, Cc. Water	Forcible Inspira- tion, Cc. Water	Forcible Inspira- tion with Glottis Closed, Cc. Water
Case 1 .....	—5	—9.5	—13
Case 2 .....	—6	—12	—14
Case 3 .....	—3.75	—9.5	—11.25
Case 4 .....	—2	—5.25	—11
Case 5 .....	—3.25	—13.75	—10
Case 6 .....	—4.75	—7	—14
Case 7 .....	—6.5	—8.5	—15
Case 8 .....	—3	—7	—3.25
Case 9 .....	—2.75	—5.25	—20.25
Case 10 .....	—2.5	—6.75	—17.75
Case 11 .....	—4.5	—6	—13.25
Case 12 .....	—7.5	—18.5	—17

air, have fluctuations of negative pressure well within the normal limits stated. However, after injection of air, patients with pleural pathologic conditions, such as adhesions, fluid, blood or pus, will show a more definite change in the reading to the more positive side of pressure after the injection of only a few centimeters of air.

### TECHNIC OF ADMINISTERING DINITROPHENOL

*To the Editor:*—Please send me information on how to administer dinitrophenol according to the weight of patient.

A. L. DELANEY, M.D., Livingston, Texas.

*ANSWER:*—Because of variations in the susceptibility of patients to dinitrophenol, the drug has usually not been given on a weight basis but rather by the system of starting with a small, ineffective dose, which is gradually increased until the desired response is being obtained. By the latter system the initial dose is 0.1 Gm. (1½ grains) a day. This dose is increased by 0.1 Gm. every one to two weeks until symptoms supervene or a satisfactory rate of weight reduction is established. The usual daily dose finally required is from 0.3 to 0.4 Gm. In a patient weighing 70 Kg. this would correspond to from 4.3 to 5.7 mg. per kilogram (from ⅓ to ½ grain per pound). In case the dosage should be controlled on a weight basis, the initial daily dose could be 1 mg. per kilogram (⅓ grain per pound), increased gradually as required.

The importance of beginning with a small dose is worth reemphasizing, since the majority of the toxic or deleterious

side actions reported have been obtained in patients who were given full doses right from the start. The Council on Pharmacy and Chemistry has reviewed the available data on dinitrophenol and decided that it is not admissible to New and Non-official Remedies. This action was based on the large number of untoward results that followed the general clinical use of the drug. The sudden outburst of cataracts in women who had taken dinitrophenol is an additional reason why its use requires most careful consideration, the possible deleterious effects being weighed as against the possible benefits from such therapy. The cause of the cataracts is not yet established, and there is even evidence that the dinitrophenol cannot be responsible at all for them in some patients. But until this situation is more thoroughly clarified the proper thing to do would seem to be to refrain entirely from using this drug.

#### PARALYSIS OF SOFT PALATE AFTER TONSILLECTOMY

*To the Editor:*—In February 1934 I did a local tonsillectomy on a girl about 16 years of age, a simple, easy operation. She went home with instructions to remain in bed until I saw her the next day. When I saw her the next day she was lisping. She miscalled her words, which I naturally thought was caused from her throat muscles being sore and stiff following operation. This condition, however, remained after soreness had disappeared and has remained ever since. The following is a list of some of the main words that she miscalls with the way she pronounces them, as nearly as I can spell them:

The—zee	F—wes	Embarrass—rebraris
Study—swawee	Say—sway	Saturday—Swaverway
Looking—wookin	Good—dwood	That—zat
Walking—wawin	Sir—swer	Tri—twi
Language—wanwage	Because—twase	Tried—twied
T—twee		

She has very little scar tissue or contraction. It has proved baffling to every one who has examined her. If you have ever had a case similar to this reported and have a packet describing same I would like to see it.

J. D. THOMPSON, M.D., Port Arthur, Texas.

**ANSWER.**—Tonsillectomy, as far as can be determined, does not have lisping as one of its sequelae. If this patient is truly lisping, one would have to assume that the speech defect had been present prior to the operation or, if it came on afterward, that it was in the nature of some psychic rather than of a physical reaction to trauma. From the given list of mispronounced words, the impression is obtained, however, that the defect is rather that produced by a paresis or paralysis of the soft palate. In other words, it is the voice of rhinolalia aperta. Paresis or paralysis of the soft palate following tonsillectomy is not infrequent, but it usually disappears within a short time. Some stubborn instances have been noted to last for weeks and sometimes months, but it is rare to have it last as long as it has in this case. It would be advisable to observe the palate to see whether it moves properly on phonation; and the services of a speech defect specialist could well be employed.

#### LYMPHEDEMA

*To the Editor:*—A married woman, aged 31, has a swelling of her left limb, which began seven years ago, extends to halfway between the knee and the hip, is slowly getting larger, pits only slightly on pressure, and is painless except for a dull and slight ache. There is a feeling of weight in the limb, which is slightly colder than the other limb. At first it used to disappear over night but it does not any more (the morning size is about the same as in the evening). Sensation is normal. There is no discoloration. The patient has been a housekeeper for the last five years. At the beginning of her trouble she was a clerk in a store. The family history and Wassermann reaction are negative. Her physical examination reveals nothing. She has had no children. The swelling is about  $3\frac{1}{2}$  inches increase in circumference. Kindly omit name and address.

M.D., Iowa.

**ANSWER.**—Can definite trauma be excluded? Has a roentgenogram revealed normal bony structures? Is it a localized mass free from or adherent to the fascia or bone or is it a diffuse swelling of the limb up to the mid thigh? Are there any superficial veins, mottling or cyanosis? Are there any brawny patches or localized indurations? If all these questions can be answered by the negative, the diagnosis of unilateral noninflammatory lymphedema has to be considered, for which surgical excision of the muscle fascia and occasionally, if a definite lymph block can be found by suitable dyes at one point, drainage of lymph into the retroperitoneal spaces may be attempted. The lymphedema often spreads gradually into the other extremity and may end in a real bilateral elephantiasis. Such a condition must be regarded as serious and very difficult to manage.

#### ADIPOGENITAL DYSTROPHY

*To the Editor:*—A boy, aged 13, white, weighing about 116 pounds (52.6 Kg.), presents the typical fat distribution of the Fröhlich type, but while noticeable (and annoying to him) it is not present in great excess. The penis is infantile, the testes are about the size of a 2-year old's and there is a very thin growth of short, straight pubic hair. His parents are anxious to do whatever they can to help him to a normal development, and I believe they are willing to try glandular therapy even though I cannot, of course, promise results. I have seen the material published from time to time in THE JOURNAL but am still uncertain as to just what preparations and how much should be used. Could you outline a definite schedule for treatment? He is now, by the way, under treatment for oxyuriasis and mild hookworm infestation. He has been on this island for about a year; previous to that time the family lived in Maryland. There are two apparently normal brothers, aged 10 and 17 years.

M.D., Virgin Islands.

**ANSWER.**—The condition appears to be one of adiposogenital dystrophy (Fröhlich's syndrome), most often characterized by adiposity, delayed sex development, increased sugar tolerance, and occasionally mental hebetude.

Specific treatment with gland preparations has been recommended; but they are indicated only when the adiposity causes the patient marked difficulties. The fat and carbohydrate intake should be limited; the diet should consist for the most part of proteins, raw fruits, and vegetables. The amount of food consumed should not exceed the caloric requirements of the patient. The preparation that has most commonly been employed is a solution of anterior pituitary in doses of from 10 to 15 minims (0.6 to 0.9 cc.), given hypodermically; the size of the dose depending on the reaction and on the severity of the symptoms.

#### CHRONIC OSTEOMYELITIS

*To the Editor:*—In the case of a boy, aged 10 years, with a chronic (fifteen months' duration) low grade osteomyelitis of the ilium and an extension of a similarly low grade osteomyelitis of the neck of the femur, what form or forms of treatment would you suggest? The original infection, due to *Staphylococcus aureus*, was treated by autogenous and stock bacteriophage with considerable but not complete success. Would staphylococcus toxoid warrant a trial? Has there been any success reported from the use of huge doses of vitamin D in such cases? Any information you may send me about these or other forms of treatment will be much appreciated. Kindly use only initials if published.

M.D., New Jersey.

**ANSWER.**—Chronic osteomyelitis may be kept active by the presence of sequestrums, cavities or sclerosed bone in which low grade infection is extensively infiltrated. *Staphylococcus toxoid* has been reported to increase the resistance of the patient to a particular organism and in that way may prevent spread or extension of the disease. There is little evidence that it has any effect in sterilizing chronically infected bone. There is no evidence that large doses of vitamin D have any specific therapeutic effect in the treatment of chronic osteomyelitis.

Physicians throughout the country who have been most successful in the treatment of chronic osteomyelitis in any region of the body have found that adequate surgery was necessary in order to obtain healing. Diseased or devitalized bone should be removed and cavities obliterated. It is sometimes advisable to excise the major portion of the diseased ilium. Partial osteotomy of the neck of the femur is likewise frequently necessary in order to obtain healing. After adequate surgery, regardless of what type of dressing or medication is used, if the general health of the patient is promoted by a supportive program of rest and sunshine, fresh air, and high vitamin, high caloric diet, healing may be anticipated with a reasonable degree of certainty.

#### SCARLET FEVER IMMUNIZATION

*To the Editor:*—There has been considerable dispute in Gary as to the value of scarlet fever immunization. Will you kindly inform me as to the latest consensus with regard to the value of these immunizing injections?

JOSEPH GOLDSTONE, M.D., Gary, Ind.

**ANSWER.**—The answer rests to a considerable degree on one's interpretation of what constitutes scarlet fever. If a rash is essential for a diagnosis of scarlet fever, the Dick method for active immunization must be regarded as highly efficient.

Inoculations with Dick toxin do not prevent streptococcal infections. It is sometimes claimed that the scarlet fever toxin merely desensitizes an individual to the rash of scarlet fever but does not prevent the disease. Notwithstanding this criticism, inoculations with scarlet fever toxin have apparently greatly diminished the frequency of scarlet fever among employees in hospitals for contagious diseases.

Many physicians believe that the Dick method of active immunization against scarlet fever is of unquestioned value and yet hesitate to recommend the procedure because of the fear of severe reactions.

Inoculation with scarlet fever toxin is now a common procedure in hospitals for contagious diseases for the purpose of immunizing susceptible nurses and others who are brought in direct contact with scarlet fever patients. The method is also required for all nurses found to be susceptible according to the Dick test in many hospitals for noncontagious diseases. Since the adoption of such measures, there is no doubt that there have been far fewer reported cases of scarlet fever than were previously observed in the same hospitals prior to the use of the Dick toxin for the purpose of active immunization.

#### CEVITAMIC ACID AND COLITIS

To the Editor:—A man recently took two tablets three times a day of cevitic acid (ascorbic acid), the synthetic vitamin C Roche preparation, for general tonic effect. After taking eight doses he developed a severe acute colitis, which cleared up after a few days of the usual treatment. There was not a history of indiscretion in diet prior to the attack. Could this preparation cause irritation of the colon? Please omit name.

M.D., Illinois.

ANSWER.—Vitamin C tablets have thus far not been reported to have such untoward manifestations as described. The colitis may have been incidental rather than a consequence.

#### REMOVAL OF PIGMENT FROM SKIN

To the Editor:—In Queries and Minor Notes in THE JOURNAL, October 10, page 1241, there is an answer to a query concerning the removal of pigment from the skin. In this it is stated that "the reducing fluid used for removal of silver from the skin is one composed of a solution of potassium ferricyanide and sodium thiosulfate in water." This is not a reducing fluid but an oxidizing one. The metallic silver is oxidized to silver ions, which then combines with chloride. The sodium thiosulfate probably merely serves to keep the silver chloride in solution long enough to be transported. The probable formulas to cover these reactions are as follows:

THEODORE CORNBLEET, M.D., Chicago.

## Council on Medical Education and Hospitals

### ABSTRACTS OF MINUTES OF BUSINESS MEETING OF COUNCIL ON MEDICAL EDUCATION AND HOSPITALS, CHICAGO, OCT. 11, 1936

1. The meeting was called to order at 10:30 a. m. Those present included Drs. Ray Lyman Wilbur (chairman), Charles E. Humiston, Frederic A. Washburn, John H. Musser, Fred Moore, Reginald Fitz, Fred W. Rankin, William D. Cutter (secretary), Herman G. Weiskotten, Carl M. Peterson and Mr. Homer F. Sanger.

2. It was resolved that the minutes of the business meeting of May 10, 1936, be approved.

3. It was resolved that West Virginia University School of Medicine and the University of Mississippi School of Medicine be placed on probation and that they be so listed in the Council's publications.

4. It was resolved that approval be withdrawn from the University of North Dakota School of Medicine without prejudice to the students now enrolled.

5. It was resolved that approval be withdrawn from the University of South Dakota School of Medicine without prejudice to the students now enrolled.

6. It was voted that the list of pathologists as submitted be approved.

7. It was voted to approve the lists of hospitals and other institutions recommended by the staff.

8. It was voted to approve the lists of schools for physical therapy and clinical laboratory technicians as submitted by the staff.

9. It was resolved that the American Board of Urology be approved.

WILLIAM D. CUTTER, M.D., Secretary.

## Medical Examinations and Licensure

### COMING EXAMINATIONS

#### STATE AND TERRITORIAL BOARDS

ALABAMA: Montgomery, June 29-July 1. Sec., Dr. J. N. Baker, 519 Dexter Ave., Montgomery.

ALASKA: Juneau, March 2. Sec., Dr. W. W. Council, Juneau.

ARIZONA: Phoenix, Jan. 5-6. Sec., Dr. J. H. Patterson, 826 Security Bldg., Phoenix.

CALIFORNIA: *Reciprocity*. Los Angeles, Dec. 16. Sec., Dr. Charles B. Pinkham, 420 State Office Bldg., Sacramento.

COLORADO: Denver, Jan. 5. Sec., Dr. Harvey W. Snyder, 422 State Office Bldg., Denver.

CONNECTICUT: *Basic Science*. New Haven, Feb. 13. *Prerequisite to license examination*. Address State Board of Healing Arts, 1895 Yale Station, New Haven.

DELAWARE: Dover, July 13-15. Sec., Medical Council of Delaware, Dr. Joseph S. McDaniel, Dover.

DISTRICT OF COLUMBIA: Washington, Jan. 11-12. Sec., Commission on Licensure, Dr. George C. Rubland, 203 District Bldg., Washington.

IDAHO: Boise, April 6. Commissioner of Law Enforcement, Hon. Emmitt Post, 205 State House, Boise.

ILLINOIS: Chicago, Jan. 26-28. Superintendent of Registration, Department of Registration and Education, Mr. Homer J. Byrd, Springfield.

IOWA: *Basic Science*. Des Moines, Jan. 12. Sec., Prof. Edward A. Benbrook, Iowa State College, Ames.

MICHIGAN: Ann Arbor and Detroit, June 9-11. Sec., Board of Registration in Medicine, Dr. J. Earl McIntyre, 202-3-4 Hollister Bldg., Lansing.

MINNESOTA: *Basic Science*. Minneapolis, Jan. 5-6. Sec., Dr. J. Charnley McKinley, 126 Millard Hall, University of Minnesota, Minneapolis. *Medical*. Minneapolis, Jan. 19-21. Sec., Dr. Julian F. Du Bois, 350 St. Peter St., St. Paul.

MONTANA: Helena, April 6. Sec., Dr. S. A. Cooney, 7 W. 6th Ave., Helena.

NEW HAMPSHIRE: Concord, March 11-12. Sec., Board of Registration in Medicine, Dr. Charles Duncan, State House, Concord.

NEW MEXICO: Santa Fe, April 12-13. Sec., Dr. Le Grand Ward, Box 693, Santa Fe.

NEW YORK: Albany, Buffalo, New York and Syracuse, Jan. 25-28. Chief, Professional Examinations Bureau, Mr. Herbert J. Hamilton, 315 Education Bldg., Albany.

NORTH DAKOTA: Grand Forks, Jan. 5-8. Sec., Dr. G. M. Williamson, 4½ S. 3rd St., Grand Forks.

OREGON: Portland, Jan. 5-7. Sec., Dr. Joseph F. Wood, 509 Selling Bldg., Portland.

PENNSYLVANIA: Philadelphia, Jan. 5-9. Sec., Board of Medical Education and Licensure, Mr. James A. Newpher, Education Bldg., Harrisburg.

PUERTO RICO: San Juan, March 2. Sec., Dr. O. Costa Mandry, Box 536, San Juan.

RHODE ISLAND: Providence, Jan. 7-8. Chief, Division of Examiners, Mr. Robert D. Wholey, 366 State Office Bldg., Providence.

SOUTH DAKOTA: Pierre, Jan. 19-20. Dir., Division of Medical Licensure, Dr. B. A. Dyar, Pierre.

TENNESSEE: Memphis, Dec. 16-17. Sec., Dr. H. W. Qualls, 130 Madison Ave., Memphis.

VERMONT: Burlington, Feb. 10-12. Sec., Board of Medical Registration, Dr. W. Scott Nay, Underhill.

WASHINGTON: *Basic Science*. Seattle, Jan. 7-8. *Medical*. Seattle, Jan. 11-13. Dir., Department of Licenses, Mr. Harry C. Huse, Olympia.

WEST VIRGINIA: Charleston, March 1. Sec., Public Health Council, Dr. Arthur E. McClue, State Capitol, Charleston.

WISCONSIN: *Basic Science*. Milwaukee, Dec. 19. Sec., Prof. Robert N. Bauer, 3414 W. Wisconsin Ave., Milwaukee. *Medical*. Madison, Jan. 12-14. Sec., Dr. Henry J. Gramling, 2203 S. Layton Blvd., Milwaukee.

WYOMING: Cheyenne, Feb. 1. Sec., Dr. G. M. Anderson, Capitol Bldg., Cheyenne.

#### NATIONAL BOARD OF MEDICAL EXAMINERS

NATIONAL BOARD OF MEDICAL EXAMINERS: *Parts I and II*. Feb. 9-11, May 10-12, June 21-23, and Sept. 13-15. Ex. Sec., Mr. Everett S. Elwood, 225 S. 15th St., Philadelphia.

#### SPECIAL BOARDS

AMERICAN BOARD OF DERMATOLOGY AND SYPHILOLOGY: *Written examination for Group B applicants* will be held in various cities throughout the country, April 17. *Oral examinations for Group A and B applicants* will be given in Philadelphia, June 7-8. Sec., Dr. C. Guy Lane, 416 Marlborough St., Boston.

AMERICAN BOARD OF INTERNAL MEDICINE: *Written examination* will be held simultaneously in different centers of the United States and Canada on December 14 and in March. *Practical examination* will be given in St. Louis in April and at Philadelphia in June. Chairman, Dr. Walter L. Bierring, 406 Sixth Ave., Rm. 1210, Des Moines.

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY: *Written examination for Group B applicants* will be held in various cities throughout the United States and Canada, March 6. *Practical, oral and clinical examinations for Group A and B applicants* will be held at Atlantic City, N. J., June 7-8. *Applications must be received at least sixty days prior to the examination dates*. Sec., Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh (6).

AMERICAN BOARD OF OPHTHALMOLOGY: Los Angeles, Jan. 23. Sec., Dr. John Green, 3720 Washington Blvd., St. Louis, Mo.

AMERICAN BOARD OF ORTHOPAEDIC SURGERY: Cleveland, Jan. 9. Sec., Dr. Fremont A. Chandler, 180 N. Michigan Ave., Chicago.

AMERICAN BOARD OF OTOLARYNGOLOGY: Philadelphia, June 7-8. Sec., Dr. W. P. Wherry, 1500 Medical Arts Bldg., Omaha.

AMERICAN BOARD OF PSYCHIATRY AND NEUROLOGY: New York, Dec. 29-30. Sec., Dr. Walter Freeman, 1025 Connecticut Ave., Washington, D. C.

AMERICAN BOARD OF RADIOLOGY: Atlantic City, June 4-6. Sec., Dr. Byrl R. Kirklin, Mayo Clinic, Rochester.

## Missouri June Examination

Dr. E. T. McGaugh, state health commissioner, reports the written examination held in St. Louis, June 4-6, 1936. The examination covered 14 subjects. An average of 75 per cent was required to pass. One hundred and ninety-one candidates were examined, 190 of whom passed and one failed. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
Howard University College of Medicine.....	(1935)	81.6, 82.8, 84.4, 85	81,
Loyola University School of Medicine.....	(1936)	83.6	83.6
Northwestern University Medical School.....	(1936)	85.6	85.6
University of Illinois College of Medicine.....	(1936)	85.2, 86.3	85.7,
University of Kansas School of Medicine.....	(1930)	(1932) 83.8, (1935) 87.4	85.7,
University of Louisville School of Medicine.....	(1934)	84.3	84.3
Harvard University Medical School.....	(1920)	85.3, (1935)	86.2
St. Louis University School of Medicine.....	(1935)	86.5, (1936) 79.3, 80.2, 80.6, 80.7, 81, 81.1, 81.5, 82, 82.1, 82.2, 82.3, 82.4, 82.5, 82.6, 82.6, 82.6, 82.7, 82.7, 82.9, 83, 83, 83.1, 83.1, 83.2, 83.5, 83.5, 83.6, 83.6, 83.7, 83.7, 83.8, 83.8, 84, 84, 84.1, 84.2, 84.2, 84.2, 84.3, 84.3, 84.3, 84.7, 84.8, 84.8, 84.9, 85, 85.1, 85.2, 85.3, 85.3, 85.4, 85.5, 85.5, 85.6, 85.7, 85.8, 85.8, 85.9, 86.1, 86.1, 86.1, 86.2, 86.6, 86.7, 86.8, 86.8, 86.8, 87, 87, 87.1, 87.3, 87.4, 87.5, 87.6, 87.9, 88, 88.1, 88.1, 88.4, 88.6, 89, 89.2, 89.3, 90.2	86.5,
Washington University School of Medicine.....	(1934)	88.7, (1935)	86.5,
Creighton University School of Medicine.....	(1935)	83.5	83.5
University of Nebraska College of Medicine.....	(1936)	83.4	83.4
University of Pennsylvania School of Medicine.....	(1935)	86.1	86.1
Meharry Medical College.....	(1935)	82.9	82.9
University of Tennessee College of Medicine.....	(1934)	82.7	82.7
University of Wisconsin Medical School.....	(1934)	87.6, (1935)	87
University of Western Ontario Medical School.....	(1936)	86.3	86.3

\* Verification of graduation in process.

## Iowa June Examination

Mr. H. W. Grefe, director, Division of Licensure and Registration, reports the written examination held by the Iowa State Board of Medical Examiners in Iowa City, June 2-4, 1936. The examination covered 8 subjects and included 100 questions. An average of 75 per cent was required to pass. Ninety-one candidates were examined, all of whom passed. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
State University of Iowa College of Medicine.....	(1936)*	80.4,	80.4,

## Social Medicine and Medical Economics

## THE PERSUASIVE APPROACH WITH THE INFECTIOUS SYPHILIS CARRIER

## A Study in Public Health Method

LOUISE BROWN INGRAHAM  
PHILADELPHIA

The sterilization of the infectious syphilis carrier is a study of known and unknown. The problem is one that proceeds from the known syphilitic person to the identification, examination and treatment of the unknown. Compulsion and persuasion are two mediums of accomplishment. These may be applied separately or integrated. My purpose in this paper is the examination of the volitional or persuasive approach largely divorced from compulsion. Intrusion on the privacy of the patient and the use of his confidential disclosures are important considerations in applying this method. The voluntary approach implies freedom of initiative on the part of the follow-up personnel in developing a personalization of appeal. It involves experimentation in technics of persuasion. The confidence of the patient and his voluntary response are entirely dependent on the development and application of these skills.

In a syphilis clinic, in a teaching institution in a large city, one is presented with an amazing array of varied racial, psychic and sexual types. Actually no two cases present exactly the same problem nor can they be dealt with in strictly identical fashion. None the less, for the sake of discussion, an attempt at broad classification seems desirable.

Both colored and white people present, in clinical practice at least, three more or less consistent character types: the settled, the unstable and the migratory. With reference to sex conduct and mode of life, on the other hand, the two races vary considerably. Among the colored it has been found that patients fall largely into the following groups: openly promiscuous individuals, usually single; persons entering into temporary liaisons for economic or social advantage, and those common-law and legal marriages which often result in varying degrees of fidelity and permanence. The white people with whom I have dealt include the secretly promiscuous person, the stable family group and the irresponsible ne'er-do-well. I have purposely omitted the formal classification of "prostitute," since these observations have been guided by the patients' own estimate of their relation to society. Only one of the patients represented herself outright as a prostitute.

The colored patients seem to have accepted syphilis, or "bad blood," as an inevitable weakness of the flesh, mercifully free from stigma or disgrace. In fact, the idea that minor illnesses of all sorts are dependent on blood disease is becoming so increasingly prevalent among the clinic type of colored patient

From the Social Service Department, University Hospital, Lena R. Waters, director, and the Department of Dermatology and Syphilology, University of Pennsylvania School of Medicine, John H. Stokes, M.D., director. Aided by a grant from the Milbank Foundation.

that little restraint is needed in opening with them a discussion of their disease. But from the white people one learns the vacillation, suspicion and resentment that syphilis breeds.

The clinic from which this study was made is very accessible to a colored neighborhood of fairly stable individuals, employed in good times; it is convenient to a neighborhood of colored homes of the better type. A few patients come from the colored commercial districts and the neighborhoods of transience. Our white patients, included in this study, are drawn from all sections of the city and its suburbs, where the reputation of the hospital is known. One worker who covers this entire area from which so many classes of syphilitic patients are gathered cannot be said to become greatly familiar with the individual aspects of neighborhood infection. Still, it is possible for the clinic and the individual worker to gain a reputation in some accessible districts, as will be shown elsewhere in this paper.

Two hundred and one cases of early syphilis were used in this study. One hundred and forty-three patients were Negroes and fifty-eight were white persons. Because of the nature of this investigation, only one case was referred to the local board of health and this was done when persuasive methods had resulted in failure. In contact tracing, varying numbers of out-of-town sources are bound to occur, necessitating the occasional employment of out-of-town agencies. I have made no effort to evaluate the efficiency of the method and type of approach employed by other organizations.

#### IDENTIFYING CONTACTS

The voluntary approach as interpreted in this study is not a feeble touch and go process. Rather is it a tender but direct cultivation of the interest of the patient sometimes through friendliness, sometimes through sympathy, often by a generous performance of some personal service. There must be a quick intuitiveness to grasp opportunities, to sense resistance or change in attitude, with a readiness to advance, to retreat, to withdraw. The attention to the patient's interests cannot be transitory; a caring today, tomorrow forgetting. It must result in a constant watchful stimulation during the entire interval required for case finding. The subject must be kept alive or the patient will forget and cease to bother.

The preparation of the patient for the contact interview is an important and easily overlooked procedure. The physician's examination and frank discussion of the disease problem from a public health point of view should always precede the contact interview. The initial confidence which only the physician is able to inspire puts the patient in a receptive state of mind for the actual mechanics of tracing the transmission of his infection. He is already turning over in his mind the details of his exposures when he meets the social worker in her office.

It has always been the policy of this clinic to bring the patient and the social worker together with the least possible delay, preferably on the day the disease is diagnosed. Time was thought to be of great importance in learning the identities of exposures. An examination of success with patients forces us to a different conclusion. We were successful in getting identities of contacts with 41 per cent of the patients who were interviewed on the same day they registered. At times subsequent to their first visit to the clinic 62 per cent revealed contacts to their infection when interviewed (table 1).

Perhaps it is asking too much to expect the syphilis patient to be in any frame of mind to reveal much of his personal experiences on his first harrowing day in the clinic. His anxious fears have been confirmed by the physician's diagnosis; he has run the gantlet of admission routine and has been the victim of painful procedures. With the healing processes of time and arsphenamine, he will be in a more favorable state to discuss the sociological phases of his infection on a later visit to the clinic. First failures do not close the investigation but pave the way to further cultivation of confidence.

#### THE FIRST INTERVIEW

The initial interview is the foundation of all our hopes for success with the individual who has syphilis. It involves an interpretation to the patient which will enable him to accept syphilis as his present illness. It is the basis for his observance of infectious precautions. It is an attempt to forestall his lapse from treatment. It may uncover personal problems that limit his ability to undertake the treatment. It prepares and often completes the necessary arrangements for the examination of contacts. In fact, I suggest that the intelligent interpretation of syphilis may even mean the beginning of effective person to person propaganda for the control of this disease.

Dr. Gerald Pearson<sup>1</sup> says "The development of a positive type of relationship is as important for rapport between the syphilis patient and his physician as in the early stages of psychiatric treatment." The social worker, as the busy physician's assistant, interviews on a personal level and lays the ground work for a long time relationship with each patient.

It is only fair, and it is also an advantageous mode of approach, to give the patient to understand that he has valid and, in fact, excellent reasons for disclosing his personal experiences. The interpretation of the syphilitic patient's duty to the community should be logical and convincing. The prevalence of syphilis and its unsuspected presence in the community is therefore explained to each patient with understandable simplicity. A feeling of responsibility for warning others and preventing suffering can be developed in most patients. Before the names of exposures are asked for, the patient is convinced

TABLE 1.—*Value of the Delayed Interview Compared with the Value of an Interview of the Patient on the First Visit to the Clinic*

	Total Inter- views	Interviews Productive of Loatable Contacts, Number	Per Cent

Patient's first interview subsequent to admission.....	66	41	62

of his good fortune in discovering his own illness while it can be controlled and has developed a sympathy for other victims of syphilis ignorant of their infection. The patient is assured of his freedom from guilt in unwittingly exposing others, and thus his infector similarly may be held blameless.

Effort should be constantly directed toward teaching the patient the manner in which he may seek out his own contacts and persuade them to report for medical examination. The technic just described and readily understood by the majority of patients suggests the use of a similar method in their own activities outside the hospital. If the patient's confidence is won, he willingly trusts the social worker to act through him in getting contacts examined. In the event that the patient remains unwilling or unable to approach his contacts himself, this task becomes the duty of the specialized clinic personnel.

Our 201 patients with infectious lesions of early syphilis were questioned immediately regarding their exposures. Exclusive of duplication, 114 (56.7 per cent) of those interviewed gave information usable in contact tracing. These 114 interviews resulted in the identification of 174 contacts, a rate of 1.5 contacts per productive interview (table 2). It will be seen from these figures what a large proportion of voluntary response can be expected from confidential interviewing.

In a city of a population of about 2,000,000, some 300,000 of which are colored, the complete identification of contacts with

1. Pearson, G. H. J.: Syphilis: Some Psychologic Aspects of Treatment, *Arch. Dermat. & Syph.* 23: 1021-1030 (June) 1931.

names and addresses might appear more difficult than in smaller communities. Smith and Brumfield,<sup>2</sup> however, in a study from the University of Virginia Clinic, obtained from 119 people the names of 196 contacts, exclusive of duplicates. A comparison of this with our results makes it seem evident that the type of community has little effect on the response of the individuals.

LOCATING CONTACTS

For the purpose of analysis I have separated the efforts in this study into the following categories: identifying, locating and persuading. The identification of contacts is done through the office conference. Locating them is the business of the patient and social worker outside the office. The persuading of the contacts to submit to examination follows their identification and location.

The question of who is to take the initiative in getting the contact in for examination is decided by agreement between the social worker and the patient after the name of the contact has been secured. Our major emphasis is always on the patient's direct appeal to his consort. The alternative in approaching the contact is through the social worker's visit, made with the approval and permission of our patient. Having counseled the patient as to attitude and approach, we suggest the mechanics of securing medical examination. The contact may seek private

syphilis therefore learns to temporize while finding out what kind of people his "prospects" are. They seldom respond to the clumsy truth, but they may yield to charm. Sincerity and sympathy for the feelings of the person must be genuine to carry conviction. A verbal generality regarding the contagiousness of infectious diseases is a good beginning for the interview. It can be suggested, for example, that an infectious epidemic has been discovered to be prevalent in the community. Certain persons are believed to have suffered exposure and are welcoming the opportunity to avoid illness. In the process of protecting the public, the hospital is confidentially advising individuals to undergo examination. Not "What is the disease?" but "Who told?" has been the first question put to the social worker. The fear of detection and threat of resentment are both embodied in this question. How it is answered may determine the course of the remainder of the interview. It can be observed here that the willingness of the original patient to have the social worker identify him as the informer usually implies his intentional indifference to the good will of his contact. If this is true, revealing the name of the informer may put the contact in the position of accused and reward the worker with a blanket denial. This has been observed in several instances when the person subsequently registered for examination and was inadvertently told that a certain named patient informed on him.

To conceal with diplomacy the name of the informer is therefore essential, and it lessens the possibility of mistaken identity. Yet when this information is withheld the contact is deprived of a degree of satisfaction, and his confidence in his interviewer's good intentions is shaken. His train of thought must therefore at once be directed along another line. To draw on his sympathy by suggesting the guilt and humiliation he would feel if he were held responsible for infecting some one is to stir his imagination and save the day. Reluctance to be identified implies the apologetic attitude of the unknown partner, while establishing the knowledge of a sense of responsibility on his part. It changes the emphasis from accusation to communication. The contact senses protection, and confidence matures. Many are quick to accept the validity of a request for examination without detailed explanation. Others open the way for an intimate discussion of their experience and exposures to infection.

A more aggressive technic possibly would give greater immediate reward but at the same time would almost certainly sacrifice valuable future gains.

REFERRING OF NONRESIDENT CONTACTS

Large numbers of people in any city are transient and migratory. Philadelphia is notably possessed of a colored population many of whom migrate from the South in search of employment; this failing, they return whence they came. It is a center for commerce with many smaller communities. Twenty per cent of our patients with early syphilis believed their infections to have been acquired out of town. Addresses and identification of their contacts were therefore referred with patient's permission to health officers elsewhere by correspondence. Fifty-three per cent of the identified out-of-town contacts were examined in their own communities as a result of these communications. Fourteen of the local contacts were reported to have left town before word could reach them.

AMOUNT OF EFFORT REQUIRED FOR ARRANGING CONTACT EXAMINATIONS

The expense in time and effort required for arranging examinations of contacts is important in the program of a syphilis clinic. The study described here was undertaken by one full-time medical social worker from the social service department of the University of Pennsylvania Hospital assisted by the physicians in the Syphilis Clinic. The interviews, visits, letters and telephone calls of the clinic social worker are the only

TABLE 2.—Results of Attempts to Identify and Trace the Contacts of 201 Early Infections Cases of Syphilis Obtained Through Routine Clinic Examination

or clinical observation by making connections of his own choice, but always we wish to be certain that he has actually sought medical care. Hence the patient is asked to bring us the address of the examining physician. For a clinical examination we offer the services of our own staff and provide the patient with an admission ticket to be given his contact. Contacts who cannot be reached with ease are referred to health agencies in their own communities. Patients understand that we cannot be responsible for tactics other than our own. Of the 174 contacts identified, 139 were located by the patient, social worker and other agents.

PERSUADING

If the title of this paper is to be logically supported, the use of coercive measures must be excluded from consideration, for we are testing what voluntary communications and voluntary responses may be obtained by our own persuasive efforts from persons who have syphilis and from those they have exposed.

The ultimate finding of the whereabouts of the contact is the outcome of the usual methods of searching a neighborhood. Clues, however meager, are ever a challenge to imagination and resourcefulness. Lack of information regarding the individual and the possibility of error in identification offer much uncertainty at best. Face to face with the suspected person, it is not he but the social worker who is "on the spot." A little daring and a nice humility are needed for such an occasion.

It is probable that the contact visit is one of the most slanderous of all social approaches. The worker hunting infectious

2. Smith, D. C., and Brumfield, W. A., Jr.: Tracing the Transmission of Syphilis, J. A. M. A. 101: 1955 (Dec. 16) 1933.

ones recorded here. The activities of physicians, health officers and other cooperative agencies cannot be tabulated for obvious reasons.

Of the 174 persons sought, 139, or practically 80 per cent, were located, and 128 (73.5 per cent) were eventually persuaded to submit to examination for syphilis (table 2). The contacts represented in our group are largely limited to the sexual partners of the infected persons. A few infants born under the expectation of infection are among the examined. There are no duplications.

It is impossible to measure the quantity of proffered information against the patient's actual knowledge concerning his sexual exposures and his willingness to divulge these secrets. Marital partners often protest their fidelity to each other. One of the

TABLE 3.—Efforts to Locate and Arrange Examination for 174 Persons Exposed to Syphilis

	Inter- views	Home Visits	Tele- phone	Total
Identifying.....	363	7	1	371
Locating and persuading.....	...	147	71	240
Totals.....	363	154	71	611

first symptoms of syphilis has been described by Wile as "loss of memory." Public health work in tracing contacts is often subject to personal resistance. Propaganda, education and persuasion, however, by stimulating public enthusiasm, will tend to minimize this personal resistance.

It is, however, impressive that 92 per cent of the candidates who were personally approached regarding an examination responded to the proposal, a figure which in itself points out the significant importance that persuasive methods may play in "case finding." Activities in the office, including interviews, telephone calls and letters, were sufficient to result in the examination of seventy-one contacts (55.4 per cent). These activities included the full use of the original patient in reaching his contact, the ultimate enlistment of the services of local and out of town agents, and the final confirmation of the contacts' voluntary examinations elsewhere. Fifty-seven contacts (44.6 per cent) required an eventual home visit for the successful arrangement of medical examination for syphilis.

The expense to the clinic of arranging contact examinations can be estimated on the basis of interviews, visits and letters. The extent to which the original patient can be made use of in securing contacts depends on the skill of the interviewer. Thus, a worker whose equipment includes such ability to use the patient will prove an economy in the undertaking. Interviews conducted by a trained social worker are estimated to cost a dollar an hour, the average salary of such a person being \$1,800 a year. Based on this figure, 363 interviews requiring approximately one-half hour each recorded in this study would amount to \$181. Successful follow-up visiting was estimated by Pugh, Stokes, Brown and Carnell<sup>3</sup> in 1930 to cost \$5.99 per patient.<sup>4</sup> Applying this to fifty-seven contacts, who, after a home visit by the social worker, were successfully persuaded to be examined, the sum of \$341.43 may be added. Ninety-seven additional visits may be estimated at \$1.40 per visit (salary, carfare, operation of automobile) on the basis of the same study. Telephone calls costing \$3.15, and letters \$7.81, complete a total of \$669.19.

It would appear, then, that an accomplishment of 128 contact examinations cost approximately \$5.22 each to arrange, the expense taking account only of recorded services.

#### THE PERSUASIVE APPROACH METHOD APPLIED

The contacts of the patients in this study largely chose the same hospital for their medical examinations (table 4). The outcome of the study and our growing experience leads us to think that a favorable reputation credited to the hospital of their choice or its representative and proclaimed by patients among their neighbors and friends greatly promotes the success of contact activities. Confidence and good will ensuing on a number of years' acquaintance in one neighborhood resulted in easy identification of contacts and immediate medical care for the infected. The importance of this friendly persuasive approach is well illustrated in the following instance, wherein many contacts were made through communications and assistance of neighbors who were our patients:

When Ellen B. was diagnosed as having secondary syphilis, darkfield positive, in the University Hospital she named her girl friend and another youth as possible sources of infection. Ellen was a frail, unattractive, 13 year old colored girl, referred to clinic by the Board of Compulsory Education after exclusion from public school because of a positive serologic reaction and suspicious pregnancy. She lived with her alleged brutal father and her truant, delinquent girl friend in a street notorious for immoral and insanitary living conditions. She indicated that the girl friend had been "sleeping" with her (the patient's) father. The clinic had treated for syphilis and supervised the attendance of seven inhabitants of this tiny street prior to the discovery of the child's seduction. Local conditions had been known and deplored, but no action had been taken.

Of the nineteen colored households in this impoverished street, thirteen families, all on public relief, lived wretchedly in the tumble-down houses facing the railroad tracks. Neighborhood gangsters had converted an empty dwelling into a club, where gambling and drinking prevailed by night and day. Several of the insanitary homes had been reported to the housing commission; the conditions had been confirmed through their investigations, and some corrected.

Ellen's girl friend had been previously hospitalized forcibly and her diagnosis of infectious syphilis was readily confirmed by another hospital. The girl had disappeared; her whereabouts were unknown. The father had registered in the same hospital, but syphilis was unproved. Ellen's sister and her sister's paramour, advised immediately by the social worker to report for study, were both diagnosed as having early syphilis, darkfield positive. The sister's paramour named the original delinquent girl friend as his source of infection.

TABLE 4.—Examinations of Contacts

	Number	Per Cent
Contacts examined at the University of Pennsylvania clinic.....	91	71
Contacts examined elsewhere		
In town.....	21	
Out of town.....	16	28.9
Total.....	128	

The suspicion of pregnancy in Ellen was found justified on subsequent complete examination, and efforts were made to arrange medical examination of her seducer, Charles C. Even though stimulated by the medical social worker, the influence of Charles's elderly syphilitic father, a University Hospital patient, was unavailing in bringing about the examination. Further information contributed by relatives led to the discovery that the University Hospital had diagnosed Charles's case "early syphilis" two years before. Charles's common law wife and child, also L. Avenue residents, had been studied for syphilis in the University Hospital, the mother's active syphilis treated, the child's syphilis unproved.

Adjacent to Ellen's home lived Marion L. C. Her illegitimate, syphilitic child shortly after birth entered the University Hospital with poliomyelitis and was already under social service supervision. The syphilitic mother had once confided that, although the C. boy was no blood relative, he was her child's father and infector. In court the mother had refused to identify

3. Pugh, J. H.; Stokes, J. H.; Brown, Louise A., and Carnell, Dorothy: A Study Based on Personal Follow-Up Results in a Syphilis Clinic, of the Patient's Reasons for Lapse in Treatment, *Am. J. Syph.* 14: 438 (Oct.) 1930.

4. It is assuming that follow-up visits and contact visits require approximately the same amount of effort.

C. as her paramour, though neighborhood suspicion pointed to this youth, protected by his loyal mistress.

Mrs. Clara R., her son's paramour and son's illegitimate child residing a few doors down the street were also under social service supervision. The two women were syphilis patients in our clinic; examination of the child was negative. Three cases of active tuberculosis existed in this street.

Until the rise of the acute situation described, this neighborhood had been tolerated as chronic and inevitable. Preoccupation with case finding and clinic attendance sometimes absorbs the largest share of the worker's thought and energy when many cases of infectious disease are to be handled. Some consideration of the social conditions that contribute to illness and delinquency, however, ought to be a part of the philosophy of the contact follow-up worker when interpreting the responsibilities of public health. Potential situations should be recognized, and the community agencies skilled in handling these should be freely called on to render service.

The Bureau of Compulsory Education, the Visiting Nurse Society, the County Relief Board, the City Hospital, the Juvenile Court and the city health department were therefore presently all actively interested in this flagrant case. Equipped with such evidence of unwholesome influences, neighborhood infection and insanitary living conditions, the Social Service Department of the University Hospital presented the situation to the city department of health. Within five weeks the dwellings were razed and the street was closed, putting an end to a local focus and regional menace.

In this nest of infections there were eleven patients with active syphilis. All but one were patients of the University of Pennsylvania Syphilis Clinic. Four cases were highly infectious. Five other persons who were contacts were examined but syphilis was unproved.

Medical social supervision was continued on the infected families. In spite of an active heart lesion, undernourishment and syphilis, 13 year old Ellen was brought successfully to term and delivered of a healthy, living infant.

This case report illustrates the high incidence of unsuspected syphilis in a small population group or area, yet it was not the syphilis of a red light district. It was the syphilis of a low class community unit living under bad housing conditions and poverty. The women were not prostitutes but the unwilling victims of idleness, vagrancy and ignorance. Since the geography of the neighborhood completely concealed it from the passing public, it was denied even the controlling influence of public opinion in the simplest requirements for common decency. As a result, seduction and promiscuity, illegitimacy and infection continued without abatement or interference.

If the infection in this community had remained within its boundaries, the final action might be questioned. The destruction of these homes would mean the scattering of multiple foci of infection among the population. In actuality Ellen's girl friend had already fled; the sister's paramour had entrained for a CCC camp; Ellen had been withdrawn for protection; new faces had appeared within the group. Syphilis came and went as separated families united or individuals departed to seek benefits elsewhere.

#### COMMENT

The method used in the voluntary approach to the infectious syphilis carrier is commended by the evidence of its success. The approach may seem objectionably emotional and personal, perhaps impractical, as a teachable technic. But vested with no authority, unsupplemented by aid from local health authorities, the persuasive method as practiced in this clinic made its successful appeal directly to the character of the individual. The method drew forth neither criticism nor resentment from patients and contacts. Only one patient in the entire study group showed negative feelings. His were directed against the diagnosis and were thought to involve a dimming of pride and loss of reverence for his social code.

As it gained in reputation, the voluntary approach inspired confidence. Among the 201 patients forming the material of

the study, only three were registered under assumed names. Of the seven whose original intention was to falsify, four made amends and subsequently offered proofs of identity in pledge of loyalty prior to their discharge from active treatment. One was the self-styled prostitute. The surprising fact that the persuasive-confidential approach would discourage the desire for anonymity could not have been predicted, but if further study actually proves this to be the case, it is another strong argument in favor of this method.

Persuasion as a public health practice may be defined, then, as an offer of aid so convincingly extended and so helpfully applied as to earn willing acceptance.

The technic of initial and subsequent interviews described in some detail in the text is equally applicable in public health undertakings, in the physician's private office, in the home, in the hospital clinic and in the social service office.

The approach dips deep into the heart of the individual and society, slowly brings into the community a realization of the ominous prevalence of syphilis and makes possible a more intensive medical attack through fostering a better understanding between the patient and the physician. It appeals to the ideals of the individual, maintains his self respect and upholds his position in society.

A small organization for the treatment of syphilis can, through the use of the voluntary approach, obtain a following of faithful patients who will support its chosen public health activities and assist in the spreading of intelligent syphilis propaganda.

#### SUMMARY

The persuasive approach is the method used in contact tracing of syphilis at the clinic of the University of Pennsylvania Hospital. Its aims with the syphilis patient are to gain his voluntary disclosures of identities of recent sexual intimates, to gain his voluntary services in personally recruiting them for medical examination, and to gain his voluntary agreement to our performance of this service. On the part of the "contact" the objective is that he voluntarily seek medical examination for syphilis. A trial of this noncompulsive method was rewarded with confidential disclosures from infected patients as to names and whereabouts of contacts and these were induced to be examined for syphilis as follows:

1. Of 201 patients with syphilis, 114 identified 174 exposures, an identification rate of 1.5 per cent contacts per productive case.

2. One hundred and thirty-seven (80 per cent) of the 174 persons sought were located; 128 (73.5 per cent) were recruited for examinations. Since 128 of the 139 contacts located were persuaded to report for study, persuasion was 92 per cent effective when the individual contact could be personally reached.

- 3 The type of community has little effect on the response of individuals, as evidenced by a comparison of these figures with those obtained by other writers elsewhere.

4. In addition to office interviews with patients to obtain information, home visits were required to complete arrangements for the examination of fifty-seven contacts (44.6 per cent).

5. The communications of the clinic social worker instrumental in the accomplishment of the 128 examinations for syphilis cost \$5.22 per successful case.

6. Nearly three fourths of the people who agreed to be examined reported to the clinic where the original case was discovered.

7. Of the identified out of town contacts, 53 per cent were eventually examined through the cooperation of outside agencies.

8. A brief delay in conferring with infected patients regarding exposures did not diminish but rather increased the successful identification of contacts. Sixty-two per cent of patients revealed usable information at times subsequent to their first visit to the clinic.

9. Protecting the informant's name from disclosure was advantageous in building confidence when proposing examination for syphilis.

10. Confidence and good will, the outgrowth of several years of professional acquaintance in one neighborhood, greatly augmented the identification of contacts and the speedy accomplishment of medical care of infected individuals.

11. A neighborhood study, included in detail, shows that the sexually promiscuous woman is often not a voluntary prostitute but is frequently the prey of unhappy social conditions.

## Book Notices

**A Text-Book of Physiology for Medical Students and Physicians.** By William H. Howell, Ph.D., M.D., Sc.D. Thirteenth edition. Cloth. Price, \$7. Pp. 1,150, with 308 illustrations. Philadelphia & London: W. B. Saunders Company, 1936.

This standard work continues to be a mine of valuable information. The current edition represents a more thorough revision than has been made for some time, part of which is based on work appearing in the literature within three or four months of the date of publication. The factual material is well selected and the clear, lucid style of earlier editions is retained. Nevertheless, one is impressed with the absence of the point of view of modern physiology, particularly in the section on the nervous system. Many of the anatomic and histologic illustrations that have been carried down from earlier editions are no longer pertinent and add nothing to the value of the book. Likewise, it is doubtful whether an illustration of a spectroscopic (fig. 182) is of any value, or the large cut of the venous pressure apparatus (fig. 206). While the point is of minor importance, the adoption of a more complete, uniform and rational system of bibliographic reference would be of great convenience to the average reader. In many instances important facts are referred to an author without any reference being given to the original publication. For instance, on page 935 there is a footnote citation to the work of Park and McClure. In the text this reference is closely followed by the name of Tongue, for which there is no citation. The critical reader is conscious of a certain degree of incompleteness in most of the author's attempts to discuss chemical reactions. Whole pages are given over to structural formulas with little attempt to point out their significance. A chemist will need no explanation; but when one recalls that, according to the title, the book is written for medical students and physicians, it appears doubtful whether these inclusions will be of any assistance to the majority of readers. Likewise there appears to be little justification for the inclusion of such structural formulas as the one proposed for progesterone (p. 959) without pointing out the significance of the configuration in relation to other compounds, especially in view of the fact that this is not a proved formula. Despite these criticisms, it continues to rank high among textbooks in the English language and should be a valuable addition to the physician's library.

**On the Disturbance of the Circulation in Spinal Anesthesia: An Experimental Study.** By Oskar O. Schuberth. Acta Chirurgica Scandinavica, Vol. LXXXVIII. Supplementum XLIII. Paper. Pp. 77, with 9 illustrations. Stockholm: Kungl. Boktryckeriet. P. A. Norstedt & Söner, 1936.

Spinal anesthesia simulates shock, and for that reason the author is uncertain as to whether or not it should be used. He carried out experimental clinical investigations and thoroughly reviewed the literature. Many definitions of shock are presented and one definition was decided on for this investigation. The influence of spinal anesthesia on certain circulatory factors, namely, (1) the oxygen consumption, (2) the arterial-venous oxygen difference, (3) the cardiac output per minute and per beat, (4) the venous pressure, (5) the circulating blood volume and (6) the capillary picture, are considered, together with the influence on respiration of spinal anesthesia involving the thoracic but not the cervical part of the spinal cord. The animals, in most instances, were narcotized with urethane and pernocton. The spinal anesthetic agent was procaine to which a dye had been added. Not all the factors concerned in the

experiments have been explained. Debatable points are made: for example, the author states "The fact that the doses of novocain used after being absorbed into the blood do not affect the circulation is apparent from table 1, rabbit 105, which immediately after the first determination was given a subcutaneous injection of 0.6 cc. of 10 per cent solution of novocain and in the second determination carried out twenty-five minutes later presented almost unchanged values."

The clinical data were not as satisfactory to the author as were his experimental data. Some of the patients to whom a spinal anesthetic was administered received spinocaine (Pitkin's method), some received procaine dissolved in liquor (Barker's method), and some received a diluted solution of percaïne (Jones's method). To each patient 50 mg. of ephedrine was administered subcutaneously prior to induction of anesthesia. The author's data, however, are presented in tables and his conclusions are drawn rather cautiously. His methods of experimentation are described carefully. The best summary of the work probably is that of the author, which is as follows:

1. In this work shock means a peripheral circulatory insufficiency.
2. In experiments on rabbits, spinal anesthesia caused the following changes: (a) a moderate decrease in the oxygen consumption, (b) a slight decrease in the oxygen content of the arterial blood, (c) a considerable decrease in the oxygen content of the venous blood, (d) a considerable increase in the arterial-venous oxygen difference, (e) a considerable decrease in the cardiac output per minute.
3. The determinations in man disclosed that: (a) the oxygen consumption showed no definite changes in spinal anesthesia, though a slight decrease is probable, (b) the arterial-venous difference was subjected to an increase under the influence of spinal anesthesia, (c) the cardiac output suffered a decrease in four cases combined with a heavy fall in the blood pressure.
4. Experiments on rabbits showed that the pressure in the right auricle was subjected to no change or to a slight decrease in the cases of spinal anesthesia that were not combined with respiratory failure.
5. There is therefore reason to consider the circulatory disturbance in spinal anesthesia as shock.
6. The circulating blood volume (plasma volume + red cell volume) suffers no change in connection with spinal anesthesia in the rabbit and the cat. (The plasma volume was determined with the dye method; the red cell volume with the carbon monoxide method.)
7. The absence of a decrease in the blood volume in a fundamental manner characterizes the shock in spinal anesthesia from most other kinds of shock.
8. In experiments with rabbits the red cell hematocrit value was subjected to a decrease under the influence of spinal anesthesia. This decrease is conceived to depend upon a displacement of the corpuscular elements of the blood towards the capillaries.
9. With Sjöstrand's method for the study of the capillary content of blood corpuscles there could be found, during spinal anesthesia in the rabbit, no sure increase in the capillary content of the blood corpuscles.
10. Recording of the tidal air in spinal anesthesia in the rabbit, encompassing the greater part of the thoracic cord, discloses that it is subjected to no change owing to the paresis of the intercostal muscles. There is no support for the opinion that the fall in the blood pressure is secondary to this paresis.
11. Nor does the tidal air in spinal anesthesia in man suffer any change that can explain the considerable fall in the blood pressure that may occur.
12. Experiments on rabbits show that the respiration, even in spinal anesthesia covering the whole thoracic cord, is sufficient for the saturation of the blood passing through the lungs. The decrease in the oxygen content of the arterial blood that has been established is explained by the simultaneously falling hematocrit values.

This monograph represents a great deal of work. Since little work has been done on this particular subject, the author's problem became so great in scope that in the time that could be devoted to it he no doubt was unable to check all the criticisms that might be raised concerning the evaluation of his results. Nevertheless, it is a good contribution to the further understanding and use of spinal anesthesia and will be of interest to physiologists, pharmacologists and clinicians, and especially to those who have an interest in the questions of shock and spinal anesthesia. The text is in English.

**Contraception as a Therapeutic Measure.** By Bessie L. Mosey, M.D. Cloth. Price, \$1. Pp. 106. Baltimore: Williams & Wilkins Company, 1936.

This is a complete statistical report of the Bureau for Contraceptive Advice in Baltimore, which operated for a period of five years, encompassing more than 1,000 cases. The bureau was sponsored by the late J. Whitridge Williams. There were 1,152 white (81.1 per cent) and Negro (18.9 per cent) patients referred by physicians for medical indications, and 1,069 were given contraceptive advice. Over 60 per cent were rated of low and less than 4 per cent of high intelligence. About 88 per cent of white and 20 per cent of Negro women had used some

sort of contraception before applying to the bureau, and only 15.11 per cent had any success. More than 1,000 abortions were admitted by the group before registering, of which 37 per cent were criminally or self induced. The method of contraception adopted by the clinic was the combined use of a vaginal occlusive diaphragm and spermicidal jelly in 95 per cent of treated cases. About 45 per cent of treated patients attended the clinic and used the method successfully for periods of from six months to six years. Only 2.71 per cent of the total number of treated cases were actual failures. Physical and mental improvement was observed in women using contraception, owing to respite from childbearing and relief from the fear of pregnancy. No injurious results were noted; in fact, many cases of improved condition of the cervix were noted after one year. Sterility was apparently not caused by the use of the contraceptives employed, as evidenced by many pregnancies that occurred when the method was omitted or discarded. Because of the low mentality of a large group of women, the method is successful only in part of the entire group of dispensary patients. The report is a valuable addition to the literature on medical contraception and will prove to be of interest to practicing physicians and social workers in this field. An adequate index and bibliography are appended.

**Die Malaria: Eine Einführung in Ihre Klinik, Parasitologie und Bekämpfung.** Von Professor Bernhard Nocht, Dr. Med., Dr. Med. H. C., und Professor Martin Mayer, Dr. Med., Dr. Med. Vet. H. C. Second edition. Paper. Price, 15.60 marks. Pp. 172, with 26 illustrations. Berlin: Julius Springer, 1936.

The first edition of this book on malaria was designed originally as a series of lectures for military physicians in the World War. In the present edition the authors have continued to restrict the subject matter to facts of interest to the practicing physician. The first sections are the most extensive and are devoted to such clinical subjects as clinical manifestations and treatment in both malaria and blackwater fever. As would be expected, treatment is considered in detail and the newer antimalarial drugs are discussed. The more strictly clinical sections are followed by a general review of the entire subject of malaria. There are short summaries on such subjects as biochemical research methods for the study of malaria, pathologic anatomy, immunity, epidemiology, serology and hematology. The latter portion of the general review deals with various zoological descriptions of the malarial parasites and mosquito carriers together with a short consideration of methods of malaria control by mosquito reduction. Throughout, the material is accurate and well selected. No attempt is made to make an encyclopedia for the specialist, but it is an excellent brief summary of the whole field of malariology for the physician or sanitarian who is not a specialist in the field but wishes a general survey.

**Neuroembryology: An Experimental Study.** By Samuel R. Detwiler, Professor of Anatomy, College of Physicians and Surgeons, Columbia University. Cloth. Price, \$3.75. Pp. 218, with 107 illustrations. New York: Macmillan Company, 1936.

Speculation regarding the formative agencies that determine the growth and adult form of the body has been replaced by experimental evidence accumulated during the past fifty years by Roux, Born, Spemann, Harrison and their successors. The agencies that control the processes of growth and differentiation include mechanical, chemical and electrical factors, and the problem is to isolate these and determine the part played by each in the dynamic vital process. This volume reports the facts so far established and the conclusions to which they point. Most of the experiments here summarized were made on amphibians from egg to adult stages by the methods of experimental surgery, with which the author himself has worked so fruitfully. There is a brief history of the neuron concept and the experimental evidence in its support, with an analysis of the parts played by neuroblasts and sheath cells in the development of peripheral nerves, including studies in tissue culture and ingenious grafting of living parts. The direction taken by growing nerve fibers may be determined by chemical, electrical or mechanical agencies. In early stages, at least, the mechanical factors seem to predominate. Experiments in tissue cultures by Paul Weiss suggest to him that the structural organization of the "ground substance" in the embryo is the basic mechanism by which nerve fibers are oriented and that chemical, electrical or other factors operate indirectly by alter-

ing the physical structure of this medium. Other chapters deal with the functions of grafted limbs in terms of their nerve supply, including a summary and discussion of the experiments of Weiss on which he bases his "resonance theory" of neuromuscular action. The influence of peripheral sensory and motor nerves on central differentiation has been demonstrated by an extensive series of ingenious experiments, from which it appears that in early stages central differentiation is determined by intrinsic factors and that later peripheral influences of various kinds play an increasingly larger part. Chapter XII deals with experimental studies on segmentation, with evidence that in urodeles segmentation of the spinal cord and nerves is not primary but is dependent on the segmental arrangement of the mesoderm. In chapter XIII some interesting experiments describe how reflex behavior is modified by destruction of specific coordinating apparatus. This is a timely and authoritative summary of investigations on fundamental biologic problems in a field that is now being actively cultivated.

**Arthritis and Rheumatic Disease.** By Maurice F. Lautmaa, M.D., Consultant to the United States Public Health Service Clinic. With a foreword by Morris Fishbein, M.D., Editor, Journal of the American Medical Association. Whittlesey House Health Series, Morris Fishbein, M.D., Editor. Cloth. Price, \$2. Pp. 177, with 12 illustrations. New York & London: Whittlesey House, McGraw-Hill Book Company, Inc., 1936.

This book is the second volume in the Whittlesey House Health Series, published under the general editorship of Dr. Morris Fishbein. In the introduction, Dr. Fishbein recalls that it has been estimated that between two and three million Americans are afflicted with some form of arthritis. References to recent advances in its care are made available in this volume, which is written for the general reader. The author is well qualified to write this book; he is consultant to the United States Public Health Service Clinic and director of the department of the study of arthritis at one of the hospitals in Hot Springs, Ark., a center for the care of arthritis. The material is well arranged and well organized, the composition is excellent, and the illustrations are carefully chosen. The author discusses the merits of various forms of treatment, such as diet, massage, exercise, hydrotherapy and the application of heat, in the prevention and treatment of arthritis and related disorders. The book should be of value to all who suffer from arthritis or who have relatives afflicted with this condition. It may be safely recommended to all intelligent patients.

**Mental Nursing (Simplified).** By O. P. Nnpler Pearn, M.R.C.S., L.R.C.P., D.P.M., Deputy Medical Superintendent, Cane Hill Mental Hospital. Second edition. Cloth. Price, \$2. Pp. 328, with 23 illustrations. Baltimore: William Wood & Company, 1936.

The first half of the text has little to do with mental nursing but describes in a condensed handbook style anatomy, physiology, and medical and surgical diseases. A discussion of nursing procedure in mental disease finds only an occasional appearance in the remaining half of the book, which is largely devoted to condensed statements concerning psychology, psychoanalysis, mental disease and diseases of the central nervous system. Some of the definitions are too arbitrary; e. g.: "Dementia means weakness of mind. . . . Judgment is the mental process by which the attributes of a percept are considered separately." Although the book may be a suitable manual for the nursing staff of the hospital with which the author is connected, it contains so little material about the specific problems involved in mental nursing that one can hardly recommend it as a general textbook.

**Le fonctionnement du rein malade: Diurèse, albuminurie, edème, glycosurie. Classification des néphropathies. Recherches expérimentales et cliniques.** Par Paul Govaerts, professeur de clinique médicale à l'Université de Bruxelles. Paper. Price, 25 francs. Pp. 214. Paris: Masson & Cie, 1936.

The first part of this treatise is devoted to an evaluation of the theory of renal secretion. The author is convinced that the weight of evidence favors the theory of filtration and reabsorption. The discussion of the mechanism of diuresis is excellent, but the treatment of the nature of edema is unconvincing. The evaluation of tests of renal function is incomplete, since the author ignores the recent American contributions. The last section is devoted to the classification of renal diseases. Unfortunately he has here completely left out Addis, whose classification is so helpful to American clinicians. The subject has been

presented from the physiologic point of view because this is the best way for the clinician to understand renal disease. The author is to be congratulated on the emphasis that he places on this outlook.

**The Operations of Surgery. Volume 1: The Upper Extremity, The Head and Neck, The Thorax, The Lower Extremity, The Vertebral Column.** By R. P. Rowlands, M.S., F.R.C.S., and Philip Turner, B.Sc., M.S., F.R.C.S., Consulting Surgeon to Guy's Hospital, London. Eighth edition. Cloth. Price, \$10. Pp. 1,045, with 435 illustrations. Baltimore: William Wood & Company, 1936.

This authoritative British work was originally published in 1889. R. P. Rowlands, the senior author, has passed away since the publication of the last edition. The unfinished portion of the work in this volume for which he was responsible was completed by Mr. W. H. Ogilvie, Mr. Grant Massie and Mr. A. R. Thompson. The primary purpose of the book, according to the preface, is "to give such a detailed account of operative surgery as to be of real assistance to surgeons recently appointed to responsible positions, and to candidates for higher examinations, as well as to provide a source of reference for the busy surgeon." This the authors accomplish unusually well. Each section lays great stress on the indications for and against operation, the anatomy, the technic in step by step detail, of one or more procedures, as well as the complications, errors and dangers that may occur. This volume covers operations on the upper extremity, head and neck, thorax, lower extremity and vertebral column. In the special fields, as otology, laryngology and neurosurgery, only well established and emergency operations are described, such as the general surgeon may be called on occasionally to undertake. The book is written clearly, simply and in such detail that the descriptions are easily followed. It is beautifully and adequately illustrated. The drawings, some of them in color, greatly enhance the value of the text. This work is an asset to every surgeon, young or old.

**Hygiene Guide-Book: A Book of Exercises and Aids in the Study of College Hygiene. Book II.** By Melvin Price Isaminger, Professor of Hygiene, Oregon State College, and Clair V. Langton, Professor of Hygiene, Oregon State College. Based on The Practice of Personal Hygiene. By Langton and Isaminger. Paper. Pp. 95, with illustrations. New York & London: Harper & Brothers, 1936.

The study of hygiene in secondary schools has been advancing rapidly in the past several years. Health is a subject of interest to every one and of importance to all. This book provides the student with two features that formerly were lacking in courses on health and hygiene: a good bibliography for collateral reading and actual exercises to determine the amount of knowledge acquired. Some of the tests given may be found confusing to the student. Thus, in exercise III he is asked to grade himself daily on six points as to signs of health. The sixth point is that a healthy person should be able "to have a store of reserve energy in time of emergency." What other mark can a person give himself besides a perfect score, since he is unable to determine his reserve unless it is called on? And emergencies do not occur daily. The student who conscientiously does the exercises in this book will be exceptionally well equipped with knowledge of health facts.

**Post-Graduate Surgery.** Edited by Rodney Maingot, F.R.C.S., Senior Surgeon to the Royal Waterloo Hospital. Volume II. Fabrikoid. Price, \$45, per set of 3 volumes. Pp. 1,747-3,572, with 1,134 illustrations. New York: D. Appleton-Century Company, Inc., 1936.

The surgery of the various regions of the body is well covered in orderly fashion, making the work a handy reference book. It might have been improved if there had been more citation of the literature. Most of the standard operative procedures are well described. The cross bow incision for exposure of the cerebellum is presented, although it has now fallen into disuse. Local anesthesia is well described and especially advocated for operations on the neck. Surgical removal of all cysts of the breast is advocated, no mention being made of repeated aspiration for the management of chronic cystic mastitis. The indications for electroresection of benign hypertrophy of the prostate are much more restricted than is the practice in the United States. There is an excellent chapter on injection therapy for the treatment of hernia, hemorrhoids, hydrocele and varicose veins. The chapter on orthopedic surgery does not cover the entire field, but the commoner deformities of the extremities are well presented and open wounds of the bones, joints and tendons are adequately dealt with.

**By-Effects in Salvarsan Therapy and Their Prevention, With Special Reference to the Liver Function.** By V. Genner, M.D., Associate in Dermatology, Finsen Medical Light Institute, Copenhagen. Paper. Price, 22 Danish kroner. Pp. 360. Copenhagen: Levin & Munksgaard, 1936.

The subject matter of this book is divided into three parts. The first is an analysis of the treatment reactions in a total of 5,526 syphilitic patients seen from 1913 to 1932 in the outpatient dermatologic clinic of the Rigshospital, University of Copenhagen. The second concerns 316 dispensary patients who were carefully questioned for treatment reactions, which were then correlated with the presence of urobilinogen and bile acids in the urine. The third section details more comprehensive use of liver function tests in 108 hospitalized syphilitic patients. The information presented in this volume could have been condensed in the form of a brief article, utilizing charts. The suggestion that urine examination for urobilinogen and bile acids is an aid in the early recognition of serious treatment reactions appears to be the chief contribution of the work.

**Symptoms and Signs in Clinical Medicine: An Introduction to Medical Diagnosis.** By E. Noble Chamberlain, M.D., M.Sc., M.R.C.P., Lecturer in Medicine, University of Liverpool. With a chapter on The Examination of Sick Children. By Norman B. Capon, M.D., F.R.C.P., Lecturer in Diseases of Children, University of Liverpool. Cloth. Price, \$8. Pp. 424, with 282 illustrations. Baltimore: William Wood & Company, 1936.

Although this book is largely a digest of the literature, with little that is new, the common symptoms and physical signs of disease are completely covered. Simple laboratory and instrumental procedures have been gathered together in separate chapters for easy reference. The text is well written and there are numerous splendid illustrations. The chapters on diseases of the heart and vessels and the digestive system are complete and deserve special commendation.

**Psychoanalysis Explained.** By Dorothy R. Blitzsten. With an Introduction by A. A. Brill, M.D. Cloth. Price, \$1. Pp. 66. New York: Coward-McCann, Inc., 1936.

In the introduction of this booklet Dr. Brill says: "It is sad to say that many medical practitioners and the great majority of lay persons still have a very peculiar idea of psychoanalysis, its aims and accomplishments. . . . After reading this manuscript by Dorothy Blitzsten, I feel that the author is to be congratulated on having performed a difficult task. I am sure that the book will be of great interest and enlightenment to all seekers of the truth about Freud's psychoanalysis." The subjects of the chapters are: psychoanalysis explained, why be analyzed? how psychoanalysis works, how it is done, who is the analyst? and whence comes psychoanalysis? The reviewer was unable to find tangible data or specific information.

**Voprosy legochnogo tuberkuleza v rannem detskom vozraste.** Pod red. P. S. Medovikova i S. A. Reynberga, i pod obschey redaktsiyey direktora Instituta Yu. A. Mendeleeva. [Problems of Pulmonary Tuberculosis in Early Childhood.] Paper. Price, 5 rubles, 25 kopecks. Pp. 147, with 10 illustrations. Leningrad: Olgz-Biomedglz, Leningradskoe otdelene, 1936.

The collection of papers dealing with the various phases of pulmonary tuberculosis presented here is the result of a joint study of the department of tuberculosis, of roentgenology and of pathology of the Clara Zetkin Scientific-Experimental Institute of Mother and Child Welfare. The many sided investigation of unusually rich material at the disposal of the institute should make this presentation of interest to the pediatrician and the roentgenologist.

**The Rise of Man Through His Handiwork. Dedicated to the Posterity of Our Much Maligned So-Called Savage Cavern Ancestor.** By David Reisz. Introduction by Alfred Bosch. Bonrds. Pp. 36, with 5 illustrations. Cleveland, Ohio: Better Education Association, 1936.

Survival of man has been attributed to several factors. This author attempts to show that man exists today primarily because of his handiwork. While he fails to prove his hypothesis, he presents an ingenious explanation of right-handedness. It is because "animals are left handed" and so the animal is more vulnerable to attack by the right hand. In the case of an elephant hunt the hunter must be sure to be on the left of the animal; at least that is the impression one gets. On concluding the book the reader is still in a quandary as to what it is all about.

## Bureau of Legal Medicine and Legislation

### MEDICOLEGAL ABSTRACTS

**Medical Practice Acts: Determination by Licensing Agency of Reputability of Medical School Not Reviewable by Mandamus.**—The Illinois medical practice act (Smith-Hurd's Annotated Statutes, c. 91, sec. 12) permits a person licensed to treat human ailments without the use of drugs or medicines and without operative surgery to be examined for a license to practice medicine and surgery without restriction if the applicant presents evidence that he has completed two years of instruction in a college of liberal arts, or its equivalent, that he has completed in an institution teaching any method of treating human ailments, reputable and in good standing in the judgment of the department of registration and education, courses in materia medica, therapeutics, surgery, obstetrics, and theory and practice, and that he has completed an internship of not less than twelve months in a hospital reputable and in good standing in the judgment of the department. Omer C. Bader, the petitioner, was licensed to treat human ailments without the use of drugs or medicines and without the use of operative surgery. He applied to the Illinois department of registration and education for an examination to test his qualifications to practice medicine and surgery, claiming to have completed, at the Illinois College of Physicians and Surgeons, courses "of instruction in liberal arts for a period of two years in materia medica, therapeutics, obstetrics, surgery, and theory and practice," and, in Jefferson Park Hospital, a twelve months internship. The department refused to examine him and at his instance mandamus proceedings were instituted against the director of the department. The superior court, Cook County, James J. Kelly, Judge, directed a writ of mandamus to issue to compel the department to examine Bader, and the director appealed to the appellate court of Illinois, third division, first district.

Bader, the director contended, was not entitled to be examined because neither the Illinois College of Physicians and Surgeons nor the Jefferson Park Hospital was, in the opinion of the department, reputable and in good standing. There was no evidence introduced showing lack of good faith or prejudice on the part of the department in deciding that the medical school and hospital, respectively, were not in good standing, and the appellate court did not think that the mere fact that the department decided adversely to the petitioner constituted proof that the department's action was arbitrary or discriminatory. In the present action, the court said, Bader sought a writ of mandamus, an extraordinary remedy, and to obtain it he must show a clear and undoubted right to the relief demanded. The evidence showed that, after a full hearing, the department had decided adversely to the reputability and good standing of the school and hospital. Where an officer, in the exercise of discretionary power, has considered and determined his course of action, as the department did in this case, he has exercised his discretion and decided the matter and his action is not subject to review or control by mandamus. Surely, said the court, the exercise of this discretionary power, when once used, cannot be disturbed in a collateral proceeding.

The appellate court held that the superior court erred in issuing the writ, and the judgment for Bader was accordingly reversed.—*People ex rel. Bader v. Hallihan (Ill.)*, 1 N. E. (2d) 415.

**Malpractice: Failure to Discover Steel Particle in Eye.**—The head of a nail struck the plaintiff in his eye and he went for treatment to the Venice Industrial Emergency Hospital, a "medical office" owned and operated by the defendant physician. There he saw a physician employed by the defendant as a "resident physician," who with the aid of a magnifying glass examined the eye and found a lineal laceration of the cornea, with air bubbles present. According to the record, no attempt was made to examine the laceration to see how far it extended. Although the physician had an x-ray

apparatus in his office, he did not use it. The treatment apparently consisted of washing the eye out with a boric acid solution and the instillation of "argyrol." After ten days, the physician discharged the patient and the defendant sent to the insurance carrier of the plaintiff's employer a "Surgeon's Final Report," stating that the result of the treatment was "Recovery."

About three weeks thereafter, the plaintiff returned to the defendant's medical office complaining of pain in the eye and diminishing eyesight. The physician who had formerly attended him treated him for about seven days and then referred him to an ophthalmologist who, with the aid of an ophthalmoscope, discovered an opaque object embedded in the vitreous. It was a piece of steel, which was removed in an operation taking about ten minutes. A few days later, "the retina collapsed" and the plaintiff eventually lost the entire sight of his eye. He thereupon sued the defendant. The trial court granted a non-suit in favor of the defendant. The district court of appeal held, however, that the evidence established a prima facie case of malpractice and that the case should therefore have been submitted to the jury. [*McBride v. Saylin (Calif.)*, 48 P. (2d) 179; abstr. THE JOURNAL, Feb. 1, 1936, p. 410.]

On appeal, the Supreme Court of California adopted as a part of its own opinion the following portion of the opinion of the district court of appeal:

From the evidence in this case it is difficult to understand how a physician, looking at plaintiff's injured eye with air bubbles present and the laceration before him, could feel that he had exercised ordinary professional care and skill without making any examination to see how deeply the injury extended, or doing anything to give reasonable assurance that there was no foreign body in the eye. Dr. Bulpitt had an x-ray in his office but made no use of it in connection with plaintiff's injury. It would seem that with an injury to a portion of the human body as delicate and important as the eye, ordinary professional care and skill would at once suggest the importance of the most careful examination. In *Reynolds v. Struble*, 128 Cal. App. 716, 725, 18 P. (2d) 690, 694, in discussing the failure of a physician to use the x-ray in connection with the diagnosis of an injury, the court said: "There is further evidence that ordinary skill and care required the use of the x-ray as an essential aid to a skillful diagnosis, employing that skill and care possessed and used by the ordinary practitioner in that community. Indeed, it might be almost said that the use of the x-ray as an aid to diagnosis, in cases of fracture or other indicated cases, is a matter of common knowledge. Even the layman, when injured, of his own accord seeks the x-ray. And under the rule of *Jacobson v. Massachusetts*, 197 U. S. 11, 25 S. Ct. 358, 49 L. Ed. 643, 3 Ann. Cas. 765, the court could, in the absence of testimony, take judicial notice of this scientific advancement."

The Supreme Court agreed with the district court of appeal that the evidence established at least a prima facie case that the physician's lack of professional care and skill was the proximate cause of the loss of sight. The judgment of the trial court granting a non-suit for the defendant was therefore reversed.—*McBride v. Saylin (Calif.)*, 56 P. (2d) 941.

# Current Medical Literature

## AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers in continental United States and Canada for a period of three days. Periodicals are available from 1926 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them. Titles marked with an asterisk (\*) are abstracted below.

**Effect of Morphine on Gastric Secretion.**—Wang and his co-workers made their observations on thirty-three patients, chiefly with peptic ulcer, and two dogs provided with isolated gastric pouches. Morphine sulfate was administered subcutaneously in doses of 0.01 Gm. It was found that morphine in ordinary therapeutic dosage seems to have a fairly uniform inhibitory effect on the gastric secretion in man under fasting conditions. The reduction of the volume of the basal secretion was more marked than that of the free acidity, although in one out of every three cases achlorhydria took place for some time after the administration of morphine and in approximately half of the series there was a distinct lowering of the acidity in comparison with the fasting values. The depressive effect of morphine on gastric secretion seemed to have a close relationship with the mental state of the patient. The more drowsy he became, usually the more marked was the depression. Those who became talkative or remained active after the medication gave the least response, and, in fact, occasionally a contrary effect. It was seen that the depressive effect of morphine could be readily overshadowed by a new stimulus, whether a purely psychic one, such as the taking of food by the patient in a neighboring bed, or a chemical one, such as an injection of histamine. In the instances in which morphine seemed to act as a stimulant, the effect was a very weak one compared with that evoked by histamine or by a psychic stimulus. The dog does not react quite the same to a small dose of morphine as man. The Pavlov dog showed a transient rise in volume and acidity after the injection of morphine on most occasions, while the complete pouch dog showed more inhibition than stimulation. The amount of stimulation in both dogs, however, was far less pronounced than those evoked by either food or histamine. Tolerance did play some part, as the dogs seemed

to develop fewer symptoms with the same dose of morphine toward the latter part of the experiment. The gastric secretions, nevertheless, showed no striking changes.

**Bile Salt Therapy in Gallbladder Disease.**—Rosenak and Kohlstaedt treated sixty-three patients having disease of the gallbladder and liver with bile salts over a period of nine months. In twenty-two cases of proved cholelithiasis, pain was not satisfactorily removed by this medical treatment. However, better results were obtained in relief of constipation and digestive symptoms. In all patients with definitely proved cholelithiasis who were suitable surgical risks, surgery was recommended. The treatment was more successful in sixteen patients with cholecystitis without proof of the presence of stones. Pain was entirely relieved in a large proportion of them, and the marked improvement of digestive symptoms in all was most striking. These results compare satisfactorily with those obtained in this type of patient with surgical treatment. In twenty-five patients with symptoms indicative of gallbladder dysfunction but in whom positive evidence of actual disease of the gallbladder may be lacking, very satisfactory results were obtained. Furthermore, when bile salts were discontinued temporarily in these patients, all symptoms returned and similar results could not be obtained by means of dietary control alone or by means of cathartics.

**Clinical and Experimental Study of Lithotripsy.**—To determine the limits of crushing power of lithotrites, Twinnem employed five instruments, four of the visualizing type and one of the nonvisualizing type. In performing these experiments, the instruments were mounted on a large testing machine and equal force was applied to the jaws in opposite directions. The points on the jaw at which the force was applied were selected to approximate as nearly as possible the actual conditions of lithotripsy. In each case the break occurred at the shoulder of the movable blade. To determine the ratio of the amount of force required to crush a ball having the consistency of a urinary calculus to the diameter of the ball to which the force is applied, twenty spheres of a mixture of sand and cement were constructed, ten averaging 1.35 inches in diameter and the other ten averaging 2.07 inches in diameter. It was found that the amount of pressure required to break the spheres of lesser size averaged 1,545 pounds and the pressure required to break the larger spheres averaged 2,810 pounds. This experiment indicates that the amount of force required to crush a ball of friable consistency, such as a calculus, increases at a little more rapid rate than the diameter. Of 105 cases of vesical calculus in which operation was performed since the foundation of the Brady department, seventy-three were treated by suprapubic lithotomy with a mortality of 4.1 per cent; thirty-two cases have been treated by litholapaxy with three deaths, a mortality of 9.4 per cent. The choice of operation depends on the age and physical condition of the patient, the size and hardness of the stone, the presence or absence of urethral stricture or

associated prostatic hypertrophy, and the experience of the surgeon. In comparing the results, and particularly the mortality, of suprapubic operation and of crushing, it should be considered that the largest and hardest stones are handled by cutting and also that recurrence is more frequent following litholapaxy by reason of the fragments that remain. For the occasional operator, suprapubic lithotomy is the safer procedure. For one who has had considerable experience and has developed a proper technic, litholapaxy is the operation of choice in a large number of properly selected cases.

### Hemoglobinuric Fever: An Allergic Phenomenon.—

During a period of five years in the Magdalena river valley of Colombia, Fernán-Núñez treated fifty-two cases of hemoglobinuric fever and observed an equivalent number of such patients of other physicians. He reviews the theories of the etiology of the disease and submits evidence to support his thesis that blackwater fever is essentially of allergic origin. It is assumed to be definitely associated with infestation by Plasmodium falciparum and its phenomena to represent an allergic response to that organism, the acute paroxysms being of the nature of anaphylactic attacks. This allergy is evidently the result of a malfunctioning of the immunity mechanism in malaria, the attacks often being precipitated by quinine, which acts on the parasites to liberate the allergen in intoxicating amounts. Such attacks might also be brought on by exposure, by reinfection with malignant tertian plasmodia or by intercurrent diseases, thus partaking of the nature of an anamnestic reaction. A minute intracutaneous injection of a formalized suspension of Plasmodium falciparum (plasmodoid), or of ground plasmodia suspended in glycerin, produced a localized reaction in persons allergic to the products of the organism. Such individuals are susceptible to hemoglobinuric fever and, if they are removed systematically from malaria districts, the disease practically disappears from such areas. In nearly all the tissues of eleven patients examined at necropsy the notable presence of eosinophils was suggestive, but, as eosinophilia is somewhat common in malaria, its significance in blackwater fever is difficult to interpret. Considerable edema was observed in many organs, particularly those containing reticulo-endothelial elements in abundance, an observation that may or may not suggest anaphylaxis under the circumstances.

**Increased Cerebrospinal Fluid Pressure in Brain Injury.**—Parker and Lehman studied the cerebrospinal fluid pressure and anatomic changes following a standard laceration of the brain in dogs. Owing to a definite association between the pressure curves and the amount of subarachnoid bleeding observed, an attempt was made to separate a rise in pressure due to the increased volume of blood in the cerebrospinal fluid from a rise due to some other mechanism. The replacement of measured quantities of cerebrospinal fluid by equal amounts of blood and its separate constituents was also observed. In experimental laceration of the brain in the dog, the cerebrospinal fluid pressure varies directly with the amount of blood that escapes into the subarachnoid space and not with the amount of bleeding within the cerebrum. In spite of the previous withdrawal of an equal quantity of cerebrospinal fluid, a rise in cerebrospinal fluid pressure occurs in the dog following the introduction of a solution of hemoglobin, defibrinated blood and blood serum into the cisterna magna. The introduction of twice the quantity of blood serum will approximately double the percentage rise of cerebrospinal fluid pressure. The introduction of washed red cells produces no increase in cerebrospinal fluid pressure over a period of as long as five hours. Microscopic study of the brains following the partial replacement of cerebrospinal fluid by blood and its separate constituents reveals inflammatory changes, which are not correlated with cerebrospinal fluid pressure changes. It is probable that the phenomena reported are the result of an increase of osmotic pressure of the cerebrospinal fluid due to the introduction of blood proteins. The approach to the problem of increased intracranial pressure must include consideration of the phenomena of osmosis as operative in bloody cerebrospinal fluid.

**Empyema in Children.**—In the ten year period that Penberthy and Benson consider, 5,868 cases were classified as pneumonia, and of this number 407 patients developed empyema that required surgical drainage. The type or virulence of the pneumonia preceding the empyema is the most important factor in determining the mortality rate of empyema. Empyema occurred as a complication in 8.9 per cent of the cases classified as lobar pneumonia and in only 1.2 per cent of those classified as bronchopneumonia. The mortality of lobar pneumonia for this period was 14.3 per cent and that of bronchopneumonia 44.5 per cent. The different mortality rates of empyema reported from various cities may be explained by the variance of virulence of the epidemic of the preceding pneumonia in

relation to geographic location. A uniform procedure of treatment has been practiced in the surgical drainage of the authors' cases consisting of aspiration up to the stage when frank pus is obtained. At this time the trocar-cannula-catheter method of closed drainage is instituted under local anesthesia. Closed drainage is maintained by applying a hemostat to the end of the catheter. Aspirations are carried out every four hours. With this type of closed drainage there may be some leakage of pus around the tube, but this occurs at a time when the empyema cavity is practically empty and should be no cause for alarm or for the changing of the catheter. The original catheter is left in place usually from twelve to eighteen days, at which time it is cut and allowed to remain open as a drain. In the event of clinical evidence of retention, the catheter is replaced by a larger tube. Among the 407 patients treated by the combined form of closed and open method of surgical drainage there was an average mortality of 10.3 per cent. Of the 365 patients who survived, all were clinically cured of the empyema except three. The latter required major operative intervention. One case was classified as tuberculous empyema with a mixed infection, in which closed drainage, followed by thoracoplasty in two stages, gave a good clinical end result. One patient required an unroofing with a subsequent good result, while in the remaining patient decortication was necessary. The latter patient died twelve hours postoperatively of surgical shock. Fifteen patients required rib resection and open drainage. The average hospital stay was 48.6 days.

**Treatment of Carcinoma of Rectum.**—Collier and Ransom have endeavored to follow the methods of Miles in treating patients with carcinoma of the rectum or rectosigmoid. The diagnosis was proved in every case by biopsy or the examination of an operative specimen. It was found that 114 cases were unsuitable for radical operation because of the far advanced lesion or because of associated disease. The abdominoperineal operation was carried out in two stages on twenty-seven patients and in one stage on seventy-two patients. The greatest contribution to the success of this operation is the principle of proper rehabilitation of the patient so strongly insisted on by Miles and Rankin. The anesthetic employed has uniformly been spinal, supplemented if necessary with light nitrous oxide and oxygen. Following the operation a transfusion is given if the patient shows any signs of shock or if he fails to react satisfactorily. An advantage of the two stage operation is that the colostomy is established and working while in the one stage procedure the difficulties of regulating the colostomy are superimposed on a patient recovering from a severe operation. The average time of hospitalization after operation is twenty-seven days. The posterior wounds are healed in about three months. While the authors attempted curative operations in 49 per cent of the patients, the true operability was probably not greater than 35 per cent. The mortality has risen (26 per cent in the two stage operation and 16.5 per cent in the one stage procedure) as they have increased the percentage of those operated on. Every patient more than 65 years of age should be considered most carefully before operation is advised. Patients with marked hypertension and cardiovascular disease should probably be treated conservatively. If obstruction is not present and if plenty of time is taken to prepare the patient for operation, the mortality from the operation should not be greater than that of the two stage operation.

**Prevention of Peritoneal Adhesions.**—Ochsner and Storck report 231 cases in which papain solution was used to prevent the reformation or initial formation of peritoneal adhesions. Many of these patients were considered to have a "keloid tendency" or "adhesion diathesis," because 122 patients in the group had had previous operations, in 46.9 per cent of which the operation had been for adhesions and intestinal obstruction. The period of observation following the division of adhesions and use of papain was one year or longer in 82.1 per cent. In a total of 224 patients in which the clinical results were given, the results were classified as excellent in 186 and good in thirteen. In seventeen cases the results were classified as fair and in eight as poor. In thirty-seven cases laparotomy was repeated following the use of papain. In twenty-two of these there were no adhesions in the abdomen, although many and massive adhesions had been present prior to their division and to the use of papain; in thirteen a number of adhesions were

present, but many less than before its use, whereas in two there was a reformation of many adhesions. There is a close correlation between the clinical results (88.8 per cent satisfactory), the observations made at operations subsequent to the use of papain (94.5 per cent satisfactory results) and the experimental observations (90.9 per cent satisfactory results) done five years ago. The four deaths in the series of 231 cases could not be attributed to the use of the papain solution.

**Demonstration of Hormones in Tumors.**—Lewis and Geschickter draw no conclusions from the results of their bioassays regarding the causal relationship between the hormones and tumor formation. In certain benign lesions of the breast, such as cystic disease and fibro-adenomas, hormones may be recovered in a high percentage of cases, while they are inconstant or absent in carcinoma of the breast. The methods in use for extracting hormones from tissue do not necessarily yield the total amount of active substance from the tissue. It has been shown, particularly in regard to estrogenic substances, that various methods of extraction will yield different quantitative results or a variety of active fractions. Preliminary hydrolysis of the tissue with hydrochloric acid or injection of an emulsion of freshly ground tissue (when not too toxic) may give higher values than the routine method of hot alcoholic extraction. While the structural formula for the female sex hormone is known (ketohydroxyestrin and trihydroxyestrin), estrogenic activity has been demonstrated for a series of condensed ring compounds of similar structures which are closely related to the sterols and bile acids. A varied group of substances likewise may produce the Aschheim-Zondek reaction. The presence of these endocrine substances in new growths would seem, however, to have significance in the physiology of the growth and to explain more satisfactorily than any theory yet advanced why tissues in a new growth reproduce themselves locally and in metastases.

**Exercise in Diabetes Mellitus.**—Marble and Smith found that in the fasting patient (from twelve to fourteen hours) with severe or moderately severe diabetes who has received no injection of insulin for several hours the immediate result of exercise (running, rowing a machine or climbing stairs) may be that of raising the blood sugar level. Exercise apparently stimulates the breakdown of glycogen in the liver, with a resulting outpouring of sugar into the blood stream. It is probable that this glycogenolysis is attributable in part to an increased secretion of epinephrine caused by the exercise. The diabetic patient of today should lead an essentially normal life, with an average amount of activity. If the diabetic condition is imperfectly controlled and if the body has been supplied with an inadequate amount of insulin, exercise instead of conferring benefit may actually increase the hyperglycemia and glycosuria. For exercise to exert its maximal benefit, sufficient insulin must be available in the body at the time of exercise. Practically speaking, after he arises in the morning the logical sequence for the diabetic patient is insulin, exercise and breakfast rather than exercise, insulin and breakfast. The exercise should be mild enough so that undue fatigue is not produced. The further advantage of two, three or more additional periods of exercise during the day is obvious.

**Pathology of Cardiac Syncope.**—Nathanson states that structural changes in the heart are usually inadequate to explain either temporary or fatal cardiac syncope. There are two

Dr. Robert Hellig Librarian

U. M. C. Medical College

BAKERS

32616

physiologic mechanisms in the heart which may cause sudden cessation of the circulation: cardiac standstill and ventricular fibrillation. In the present study it was possible to manipulate the human cardiac mechanism (1) mechanically, producing cardiac standstill by reflex vagus stimulation, and (2) chemically, inducing a prefibrillation state in the ventricles by sympathetic stimulation with epinephrine administered intravenously. Both of these physiologic states may be definitely modified by drugs. Drugs of the epinephrine series in proper dosage will prevent cardiac standstill. Prefibrillation rhythm may be prevented by the use of quinidine or of acetyl-beta-methylcholine. Protection of the sympathetic nervous mechanism by general measures is indicated. The studies suggest an approach by drug therapy and by general measures toward the prevention of cardiac syncope and sudden death.

**Pathogenic Fungi.**—In twelve months Whalen encountered, in the routine of private practice, seventeen patients with verified fungous infection of the ear, nose, throat and respiratory tract. The placing of the suspected material on a glass slide, with the addition of a few drops of alcoholic solution of sodium sulfide, and covering with a cover glass is satisfactory for a wet specimen. Gram's stain is used if a stained specimen is required. Shaw's medium is made use of when cultures of the material are to be taken. Modification of this procedure will be found necessary when the identity of the fungus is obscure. After examination of the wet specimen, an attempt at cultivation may be made. The pathogenic fungi that have been found to affect the ear, nose, throat and respiratory tract have given rise to moniliasis, sporotrichosis, blastomycosis, actinomycosis, coccidioides, torulosis and aspergillosis. Other fungi have been found to be parasitic in man, such as *Coccidioides immitis*, which produces a granulomatous disease termed coccidioides granuloma. A second disease condition similar to this, termed torulosis and caused by a yeastlike parasite, *Torula histolytica*, is also classed with the infectious granulomas. Both these organisms can and frequently do produce an infection of the pulmonary system. The changes produced in pulmonary tissue are similar to those caused by tuberculosis, by actinomycosis and by aspergillosis.

**Acquired Resistance to Certain Neurotropic Viruses.**—Olitsky and his associates furnish evidence that resistance develops in some animals with increasing age only as regards certain neurotropic viruses introduced into the body by definite peripheral routes. This type of resistance is not general and systemic in nature, for introduction of the virus directly into the brain finds both young and old equally susceptible. This naturally acquired resistance was found to be most marked in old mice against the Indiana and New Jersey strains of vesicular stomatitis virus, when inoculations were made by the intranasal, subcutaneous, intramuscular, intraperitoneal and intravenous routes, but not by the intracerebral. The development of this resistance varied in different mice, becoming apparent as early as the thirtieth day of life in some and remaining absent in others even at 1 year of age. The change that renders old mice refractory to peripheral inoculation with the two immunologically distinct strains of vesicular stomatitis virus does not necessarily induce a similar state against other viruses. Thus, while the majority of older mice exhibit a similar resistance against the Western strain of equine encephalomyelitis virus, it is not readily demonstrable with the immunologically distinct Eastern strain. Nor were older animals refractory to peripheral inoculations of pseudorabies virus in guinea-pigs and poliomyelitis virus in rhesus monkeys.

**Use of Insulin Protamine in Diabetic Children.**—Boyd used insulin protamine in the treatment of twenty-five diabetic children. The usual procedure has been to observe the patient in the hospital with alternating control periods on insulin hydrochloride with those on insulin protamine. In none of the children studied was control impossible with ordinary insulin, but in some this was accomplished only with four doses of insulin a day, one before each meal and one at midnight. With insulin protamine alone or combined with ordinary insulin, equally good if not better results were achieved with two doses a day. The morning glycosuria has been well controlled if the insulin protamine is administered by the clock, 8 a. m. and 8 p. m., rather than at mealtime. Substitution of equal doses of insulin protamine for ordinary insulin, even if given by the clock, may permit some glycosuria for a couple of days, which completely disappears without any further adjustment. Reactions occur, but they are less severe and less frequent than hypoglycemia. This may be because of the more gradual fall of the blood sugar that occurs. Blood sugar estimations appear to be more urgent in the patient who is glycosuric with insulin retard than with ordinary insulin. Protracted ill feeling, such as tiredness and weakness, due to hypoglycemia is more common and is sometimes sufficiently severe to make the patient desire a return to the old insulin. This fatigue may be overcome by the needed reduction of the dose. The well adjusted patients, on the other hand, speak of increased well being and particularly about the new restfulness or peacefulness of their sleep. So far, no local reaction has been observed as the result of the administration of insulin protamine, nor has any general protein reaction occurred. Insulin protamine acts so slowly that it is contraindicated when quick action is desirable, such as in coma, when better results are obtained with ordinary insulin. Likewise in preoperative cases it should not be given, even if the patient is taking it and is being well controlled by it under ordinary circumstances.

**Influenzal Meningitis.**—Huntington and Wilkes-Weiss analyze fifty-four cases of influenzal meningitis from the St. Louis Children's Hospital and 500 cases collected from the literature. Only sixteen of the fifty-four patients were females. Only twelve of the patients were more than 2 years of age, while, of the 500 patients, 127 were more than 2 years old. In the group of fifty-four cases there were three recoveries. In the larger series there were thirty-five recoveries, twenty-six of which occurred in patients more than 2 years of age. According to the prevailing concept, influenzal meningitis is usually "primary." However, in ten cases it seemed clear that the onset of meningitis was preceded by otitis or pneumonia, and in some additional instances there were other features of interest in the recent history. In the fifty-one fatal cases the average time elapsing from first symptoms of severe illness to

death was approximately fourteen days. The longest duration in any of the authors' fatal cases was thirty-four days, and in this instance serum treatment may have prolonged the course. However, another patient, who received no serum, lived for twenty-two days after the onset of cerebral symptoms. In purulent intracranial infection in young children the conventional meningeal signs are often absent, and influenzal meningitis is no exception to this rule. One must be quick to suspect meningitis in any unexplained febrile illness of an infant. Extrameningeal lesions (abscess, pleural effusions, pericarditis, metastatic lesions, osteomyelitis, cellulitis, purpura) should be looked for. Patients with influenzal meningitis may have either a leukopenia or a leukocytosis. *Haemophilus influenzae* was found on one or more cultures in sixteen of twenty-four blood cultures. In the case of osteomyelitis of the tibia and in the cases of abscess of the extremities and of pericarditis, pure cultures of *Haemophilus influenzae* were obtained from these lesions. Definite evidence of cerebral block was observed during life in one patient and at necropsy in another. A third patient showed a pressure cone at necropsy. In most instances the spinal fluid leukocyte counts were between two and ten thousand, with a high percentage of polymorphonuclears. The highest count recorded in the series was 294,000, with 97 per cent polymorphonuclears. Stained smears of the first spinal fluid sample revealed gram-negative bacilli in all but twelve cases. In two of these twelve the first spinal fluid specimen was entirely normal but the second showed organisms on direct smear. Cultures were made in fifty-three of the fifty-four cases, and *Haemophilus influenzae* was eventually demonstrated in all of them, although first cultures were negative in two. The diagnosis of influenzal meningitis should be confirmed by culture of the spinal fluid in every instance. The diseases most likely to be confused with influenzal meningitis are meningococcal meningitis, other forms of purulent meningitis and tuberculous meningitis. In practically all instances, bacteriologic examination of the spinal fluid is necessary to settle the diagnosis.

**Congenital Atresia of Esophagus.**—In treating cases of congenital atresia of the esophagus with tracheo-esophageal fistula, Leven has carried out a procedure that attacks the fistula indirectly. The operation is done under local anesthesia. The abdomen is opened through an upper left rectus incision,

which extends up to the rib margin. The stomach is gradually retracted and packed off until the cardiac end is reached. By means of blunt dissection with a curved forceps, the subdiaphragmatic esophagus and the cardiac end of the stomach are mobilized. A rubber tissue drain is passed under the mobilized esophagus. By blunt dissection a centimeter of the mediastinal esophagus can be pulled into the abdominal cavity. By depressing the abdominal wall and exerting moderate traction on the drain, one can bring the cardiac end of the esophagus and stomach up into the wound. Two mattress sutures of chromic catgut bring the peritoneum and the rectus sheath under the exteriorized cardiac end of the stomach and the esophagus. A multiple purse string type of gastrostomy is then made in the stomach distal to the exteriorized portion. The upper and lower ends of the wound are closed with mattress sutures through the muscle and peritoneum. The skin is closed with vertical mattress sutures tied over rubber tubing. A soft rubber catheter is placed under the exteriorized segment, and the ends are fastened to the abdominal wall. An angulation is thus formed at the cardia and proximal to the gastrostomy, which will effectually prevent regurgitation of gastric contents into the lungs so that an adequate diet can be fed through the gastrostomy tube immediately. Because of leakage about the gastrostomy tube and perforations that occur in the exteriorized segment of the stomach and the esophagus, it is advisable to cut across this portion of the stomach in from two to three weeks and reconstruct the gastrostomy. A cervical esophagostomy would be done as the second stage procedure, and at a distant future date an antethoracic esophagoplasty could be carried out to establish continuity of the gastro-intestinal tract.

**Problem of Childhood Tuberculosis.**—Medearis suggests that the following be applied to routine pediatric practice: A wider use of the tuberculin test in diagnosis is advisable. Every child giving a history of home contact with tuberculosis should be so tested. Any child with inadequately explained fever or with a subnormal weight gain deserves a tuberculin test. A Mantoux test may well be made a routine procedure in every hospital admission of a pediatric patient. Every positive reactor should have a roentgenogram of the chest, and the interpretation of this plate should be made by a physician adequately trained in the roentgen diagnosis of tuberculosis. Every patient in whom a primary tuberculous complex has been diagnosed merits an adequate medical follow up with proper hygienic and dietary supervision and examinations at intervals frequent enough to assure the detection of any developing adult type or disseminating lesion early enough to establish effective special therapy.

**Uretero-Ureteral Anastomosis.**—Neuwanger devised a technic of transplanting the ureter which consists of cutting the ureter obliquely and placing a black silk stitch in the tip of the ureter; both strands are then threaded through a large straight needle and the transplantation is effected by passing the needle through the recipient tissue. This is followed in turn by the ligature and ureter. This method was found admirably adapted for repairing a cut ureter and for uretero-ureteral anastomosis. Following its use in thirty-two animals it was used on a clinical case, in which three months later intravenous urography showed the kidneys and ureter to be unchanged and an anastomosis functioning normally.

**Acute Perforated Peptic Ulcer.**—Summey limits his study to fifty-eight cases of acute perforations of the prepyloric and postpyloric regions of the gastro-intestinal tract. The youngest patient in the group was a boy of 18 and the oldest was a man of 79. Most of the cases occurred in the third and fourth decades of life. About 94 per cent gave a definite history of indigestion varying in length from one week to thirty years. The symptoms in the majority of the cases were fairly typical in those admitted within the first twelve hours after perforation with the exception of two, in which there was no rigidity and the peristalsis was normal. Only three gastro-enterostomies were performed, as the author feels that the operation for acute perforation of gastric or duodenal ulcer should be limited to a simple closure in practically all cases. By so doing the mor-

tality will be lowered and one will have time later on for a thorough investigation with the aid of a gastro-enterologist and a roentgenologist to determine whether or not more surgery is required. The operative mortality of the fifty-eight patients operated on was 20.6 per cent. The mortality rate was in direct ratio to the time interval between perforation and operation. The causes of death in the patients operated on were peritonitis, postoperative shock, intestinal obstruction, pneumonia and hemorrhage from second ulcer on the posterior wall of the duodenum. Spinal anesthesia is the ideal anesthetic if the patient has reacted from the initial shock, as patients usually do a few hours after the onset. It permits perfect relaxation, enables one to work quickly and smoothly, and makes aspiration of the soiled peritoneal cavity easy. Drainage is not indicated unless there is marked soiling of the peritoneum of a duration of more than twelve hours. Before the patient leaves the table, he is given 50 cc. of a 50 per cent solution of dextrose intravenously if required, and on his return to bed the Trendelenburg position is maintained for six hours in those cases in which spinal anesthesia has been used. The fluid balance is maintained for the next two or three days by the use of continuous venoclysis of a 10 per cent dextrose solution or by hypodermoclysis of physiologic solution of sodium chloride. The stomach is drained by suction until the pylorus becomes patent. Nothing is given by mouth for twenty-four hours. At the end of the second day the patient is given water freely. On the third day a Sippy diet is prescribed and increased until the patient takes the full Sippy regimen at the end of one week. The majority of the patients who have maintained the prescribed diet have done well; 20 per cent of them, however, still complain of some form of indigestion even though adhering to a definite ulcer regimen.

**Trauma and Cancer.**—Fowler believes that alleged "traumatic tumors" would disappear from the literature if the so-called facts given in support of them were analyzed critically in the light of inquiry under present strict criteria. One of these criteria is the great probability of coincidence. Bruises and minor wounds are so common that almost every tumor victim will be able to think back and try to blame such an occurrence. An injury sustained in a potential tumor area, as in the breast, for example, is more likely to intensify subjective symptoms and to direct attention to a heretofore unsuspected tumor. This psychologic principle is termed by Eving "traumatic determination." One may accept aggravation of a tumor only when the injury introduces into the disease significant, harmful effects that do not occur normally. The idea that injury accelerates tumor cell growth is not supported by clinical and experimental data. Trauma may cause metastases only in advanced stages, and then it does not alter the course of the disease.

**Treatment of Acute Head Injuries.**—Bates believes that lacerated wounds of the scalp should all be treated as infected wounds. The wound should be sutured loosely and drained. In those cases in which tight sutures are necessary to control hemorrhage the suture should be removed within forty-eight hours. The stab wounds inflicted with such instruments as ice picks should be considered potentially dangerous. The author has seen cases in which the pick penetrated the brain with no evidence of paralysis or any manifestation of injury

to the central nervous system. All wounds of the head in which there is evidence of soil contamination should receive the prophylactic dose of tetanus antitoxin, because tetanus following wounds of the head is more likely to be fatal. A craniocerebral injury is the most serious injury of the head. The attending nurse should understand the psychology underlying the recovery from head trauma. An injury to the brain leaves for a time a sick mind capable of running the gamut of imagination. Because of the various degrees of severity, the treatment of craniocerebral injuries cannot be standardized. An important point in the diagnosis of extradural hemorrhage is a lucid interval between the initial and subsequent loss of consciousness. In craniocerebral injuries, increased intracranial pressure is always due to hemorrhage or edema. The head injury in which no fracture is demonstrable should be thought of as a "black eye of the brain." The concussion cases usually clear up within a few hours or few days and the only treatment necessary is rest. In the more severe cases the surgeon should determine how completely nature is compensating for the increased intracranial pressure. Space compensation is the principal function of the cerebrospinal fluid. In patients with fracture of the skull and increased intracranial pressure a most careful and persistent study should be made. The treatment of shock is the first consideration with few exceptions and must be brought promptly under control. An emergency dressing must be applied to head wounds, but no wound repairs should be done that will further shock the patient. Undoubtedly the most efficient treatment in acute craniocerebral injuries with or without increase in intracranial pressure is rest. Those patients who show evidence of extradural hemorrhage with rapid increase in pressure should have immediate operation with ligation of bleeding vessels. The cases of severe trauma to the brain with increasing intracranial pressure should be treated with rest, dehydration, lumbar puncture and decompression. Under no circumstances should roentgenograms of the head be made while the patient is still suffering from shock. Dehydration can best be accomplished by limiting the intake of fluids to 600 cc. in twenty-four hours, by administering hypertonic dextrose solution and by giving magnesium sulfate. Lumbar puncture should never be used during the period of shock or to relieve pressure due to subdural or extradural hemorrhage. When rest and dehydration do not relieve the symptoms of increased intracranial pressure, lumbar puncture should be done. Its repetition should be determined by the results. The brain cannot be subjected to pressure that interferes with cerebral circulation for a considerable time without causing cerebral degeneration or death.

**Results of Sympathectomy in Angina Pectoris.**—Kerr performed superior cervical ganglionectomy in thirty cases of angina pectoris. In eighteen cases only the left superior cervical ganglion was removed because the pain was confined to the left side. In eleven a bilateral superior cervical ganglionectomy was done, as the pain was referred to both sides. In one case the distribution of pain was to the right side alone, and in this case only the right superior cervical ganglion was ablated. Of these thirty patients, two died while in the hospital, one immediately after operation and one five days post-operatively. Of the remaining twenty-eight, complete cessation of attacks of pain following exertion, eating or excitement was obtained in fourteen, stimuli that had previously produced characteristic attacks. Ten of the other fourteen patients obtained 75 per cent relief. In these cases a lesser degree of pain in the precordium was caused by exertion, eating or excitement. An occasional dose of glyceryl trinitrate was taken, but the patients were able to resume their previous life or occupation at a lesser tempo. Only slight relief, estimated at 25 per cent, resulted from operation in three cases. Former stimuli continued to produce pain of a lesser degree, but they were unable to return to work and had occasion to use the nitrites more or less continuously. One patient obtained little or no relief. Congestive heart failure was present when operation was performed. He was suffering severely and should not have been operated on. He died a cardiac death three months after operation. The ultimate outcome of superior cervical sympathectomy in angina pectoris depends on the underlying cardiac disease.

**Changes in Bones Induced by Injury.**—Brailsford urges serial roentgen studies in cases of injury to bones and joints, as they will show the stage of healing, the time when the limb can be subjected to any of its normal stresses and strains, the ultimate fate of the graft and extensive osteoporosis of the living bone unless its vascularity has been impaired. Wiring and plating will give good apposition of the fragments and union, but as long as the metal is retained the bone will not completely recover its normal strength and elasticity. Injury to the surface of a bone may be associated with the formation of a hematoma, which will not be revealed by a roentgenogram in the early stages. Some hematomas are prone to calcification in which subsequent ossification may occur. Injury to cancellous bone may not be sufficient to cause a breach of continuity of the surface of the bone but may yet lead to a localized absorption of the damaged trabeculae and produce a cystlike appearance. In some cases in which the injury has been followed by effusion into the joint it may be possible by comparative examination of roentgenograms of both joints to recognize an increase in the joint space on the affected side. In severe injuries, such appearances as pointing of the articular margins and osteophytic development around them, the formation of loose bodies in the joint, churning and erosion of the bony surfaces which have been brought into contact may be detected—in fact, all the degenerative changes associated with the term osteo-arthritis. Once degenerative changes have been indicated in a joint, serial roentgen examinations will show a slow progression of the lesion with gradual limitation of the range of movement due to destruction of the articular surfaces: but bony ankylosis never occurs unless induced by surgical resection of the articular surface and close approximation of the bared bony surfaces. If the injured joint is devoid of normal trophic influences, normal regeneration appears to be checked or abolished and the joint surfaces with the underlying bones are slowly and painlessly worn away, the liberated calcium often appearing as an amorphous deposit. These changes are frequently associated with effusion into the joint and signs of edema in the neighboring tissues. Injury to an intervertebral disk may not be apparent for several months after trauma. It may then be indicated by diminution of an intervertebral space and lipping of the adjacent margins of the vertebral bodies, and perhaps partial localized ossification of the anterior common ligament. The bones of immobilized limbs show a gradual and somewhat irregular decalcification even of those bones which were not involved by the injury. Often marked changes not only in the calcium content but in the cancellous and compact structure of the bone may be seen. Many cases of acute septic abscess, tuberculosis or gummas of bone present clinical evidence of a primary septic, tuberculous or syphilitic focus apart from the bone lesion, which often appears to have originated at the site of a definite injury. The statistics of the German army and navy show that 1 in 15,000 injuries is followed by malignant changes.

Report on Gastric Analysis and Bacteriology in Cases of Rheumatoid Arthritis, Osteo-Arthritis, Spondylitis and Fibrositis. L. J. A. Parr and Eva A. Shipton.—p. 354.

**Clinical Types of Diphtheria and Types of *Corynebacterium Diphtheriae*.**—The studies of Anderson and her associates of 184 cases of the grave type of *Corynebacterium*

diphtheriae indicates that it is widely distributed in Sydney, and that, as in Europe, this type is apt to cause a more severe form of diphtheria than the mild type. The mild type undoubtedly can give rise to malignant diphtheria, but in this series of cases the grave type caused nearly seven times as many malignant infections as the mild. This fact, and the reports of malignant diphtheria coming from the country districts, suggest that the grave type is prevalent throughout the state. This highly fatal form of the disease is generally associated with the grave (or intermediate) form of the organism, and the probabilities are that malignant diphtheria always has been associated with this type. Like other workers, the authors have failed in their efforts to throw light on the pathogenesis of malignant diphtheria caused by the grave type and fall back on the obvious suggestion that sometimes, but by no means always, the grave organism is able either to form more toxin or to form it more quickly, so that the patient absorbs a fatal dose before antitoxin is administered. In one case in this series 100,000 units of antitoxin was given intravenously and intramuscularly within twenty-four hours of the first symptoms of illness, and yet the patient died. Malignant diphtheria occurred only once in this series in a child whose tonsils had been removed. The hemolytic streptococcus is not an important factor. That there is a form of diphtheria today, which, despite antitoxin, carries a death rate of more than 50 per cent is a convincing argument for pressing forward with prophylactic immunization. Diphtheria can occur occasionally in a person who does not react to the Schick test, but the authors know of no case in which a subject not reacting to the Schick test has died of diphtheria.

**Intravascular Hemangio-Endothelioma of Ovary with Torsion of Pedicle.**—Fujii reports a case of intravascular endothelioma of the ovary, which showed sarcomatous degeneration and finally ruptured owing to congestion and torsion of the pedicle. On laparotomy, the pedicle was contorted three times, the wall of the tumor had been broken and a brownish black substance, like putrid flesh, filled the abdominal cavity with a large quantity of blood. The tumor was cut off from the uterine cornu and the contents were removed. The abdominal cavity and vagina were cleansed with ether. After 20 cc. of ether was injected into the cavity, the abdomen was sutured. Recovery was uneventful and the patient left the hospital within three weeks. She is now healthy, with no sign of recurrence one year after operation. Histologically, small vacuoles were found in the centers of the cell groups of the tumor. There were erythrocytes in these vacuoles. Congestion and hemorrhage were recognized in places in the tumor and seemed to originate from stagnation of blood brought about by torsion of the pedicle.

**Diagnosis of Hodgkin's Disease.**—Emile-Weil and his collaborators studied the tissues obtained by puncturing the glands in Hodgkin's disease. The so-called Sternberg cells were the most characteristic cells observed in these specimens. There was also extreme cellular polymorphism. Several types of adenograms are described. One of these is characterized by monocytic hyperplasia: increase in the number of typical monocytes and absence of Sternberg cells. Another type is that in which eosinophil cells predominate. If the percentage of these cells exceeds all others, one can believe that lymphogranulomatous tissue is being formed. Also a type is described in which there is massive infiltration with polymorphonuclear cells. Finally there is a type of adenogram of fibrous nature that occurs in an advanced phase of the disease. The authors conclude that ganglionic puncture is as reliable as biopsy in demonstrating the elements necessary for the diagnosis of malignant lymphogranulomatosis. Furthermore, when well studied and interpreted it offers a practical advantage over biopsy. It enables repeated examinations to be made and thus to follow the evolution of the disease in a way that is impossible when biopsy is employed.

Abdominal Contusions with Multiple Lesions of Mesentery and Mesosigmoid. G. Mandillon and J. Poinot.—p. 578.

**Bloody Effusions and Infected Wounds.**—According to Gurewitsch and Rewo, the conventional view that fresh bleeding into the tissues makes the involved area a site of predilection for infection needs review. In order to approach this problem in an experimental manner, they made a series of seven experiments on rabbits. The abdominal wall was shaved and was washed with alcohol. The following day an operation was performed with the object of producing a hematoma. In this series of seven large hematomas they failed to get any suppuration, even following the intravenous injection of various living cultures of bacteria. Thus, in the experiment they not only failed to demonstrate the susceptibility of a hematoma, but, in fact, the hematomas showed a certain degree of resistance against infection. They believe, therefore, that fresh hematomas actually increase the local resistance of tissues.

Spontaneous Pneumothorax Contralateral to Artificial Pneumothorax. J. Stephani.—p. 1088.

**Transitory Pulmonary Infiltrates with Eosinophilia.**—Löffler directs attention to fleeting pulmonary infiltrates that are accompanied by eosinophilia. This complex of symptoms apparently may develop under various conditions. The author has observed fifty-one cases, some of which he describes. The process is benign, but this contrast between the benign character of the disorder and the often alarming objective symptoms makes the process important not only from the theoretical but also from the practical point of view. The author gives his attention first to the chief symptom, the roentgen shadow. Localization, extension and structure of the shadow vary. Its main characteristic is its transitory character; it forms in a

comparatively short time and disappears again just as rapidly. A single roentgenoscopy does not permit a definite diagnosis, but it is necessary to repeat it, if possible, every second day. The second important symptom is the eosinophilia of the blood. It varies from mild to extremely severe degrees. There is no parallelism between the size of the pulmonary infiltrate and the severity of the accompanying eosinophilia. The latter may be in its severest stage at a time when the pulmonary shadow is already disappearing. The disturbances in the general condition are as a rule slight. In many cases there is a complaint of general fatigue. The acoustic symptoms are usually slight. Coughing is complained of in many cases and it may be accompanied by piercing pains. Expectoration is either entirely absent or it is slight. In discussing the pathogenesis, the author expresses the opinion that the infiltrates are the manifestations of extremely benign tuberculous processes; that is, they indicate an extremely favorable allergic condition.

**Vitamin C in Treatment of Bronchial Asthma.**—Epstein reports the results he obtained in the course of one year with the systematic administration of vitamin C as an adjuvant in the treatment of bronchial asthma. In nearly all the patients with asthma who were treated with gold salts, intravenous injections of 100 mg. of a vitamin C preparation were intercalated between the injections of the gold salt. After this combination therapy was instituted, the cutaneous or oral complications attributable to the gold salts no longer appeared. The author considers this extremely important, for, in view of this effect of vitamin C, its use is justified not only in the treatment of patients with asthma but also in tuberculous patients who receive gold therapy. In patients with bronchial asthma who gave a positive Pirquet reaction, the author tried treatment with tuberculin and vitamin C. Here too the results were extremely favorable. The author reaches the conclusion that the use of vitamin C as an adjuvant is justified in the treatment of asthma.

\*Behavior of Certain Seroreactions for Syphilis on Blood Serum of Non-syphilitic Persons Inoculated with Malaria. Ester Ferrando.—p. 502.

**Simplified Technic of Henry's Melanoflocculation.**

Spanedda reports a modification of Henry's melanoflocculation for malaria. Laked blood is used instead of blood serum. The technic is as follows: 1. A melanin suspension is prepared from fresh beef choroid. The suspension is prepared according to the usual technic and is left in the icebox for at least one month before using. 2. Two or three drops of blood from the finger of a patient with a fasting stomach is dropped into a pipet that contains 1 cc. of distilled water. The test is made within twenty-four hours after the withdrawal of the blood, care being taken that the blood solution is clear and not inactive. At the time the test is made, two alkaline solutions are prepared by adding 0.25 cc. of a solution of hundredth normal sodium hydroxide to 100 cc. of distilled water for the one, and to 100 cc. of a 3 per thousand solution of sodium chloride for the other. With the two solutions two 1:10 solutions of melanin are made from the melanin mother suspension. The latter is shaken before being used. Five identical pipets are prepared. Four drops of laked blood is placed in each of the first four pipets. Then eight drops of the solution of melanin in distilled water is added to the first pipet, eight drops of the solution of melanin in sodium chloride solution to the second, eight drops of distilled water to the third and eight drops of a 3 per thousand solution of sodium chloride to the fourth. To the fifth pipet, which contains no laked blood, eight drops of the solution of melanin in distilled water and four drops of distilled water are added. The results of the test are read with the aid of an agglutinoscope two hours later if the pipets were left in a thermostat at 37 C., or twenty-four hours later if they were left at ambient temperature. The author tried the modified test in ninety-one cases. In eighty-four the presence of plasmodia

in the blood was evident. An intermediate reaction (between the atypical reaction caused by globulins and the typical one) took place in twenty-four serums. The test gave negative results in three serums and typical positive results in sixty-four. The results were not related to the fact that the blood was taken during the febrile attack or in the afebrile stage. The only exceptions to this rule were the three cases previously mentioned, in which the test gave negative results, whereas plasmodia existed in the blood. In these cases the blood for the test had been obtained during the febrile stage. The author made the test by the modified technic as well as by the common methods in thirty serums in order to compare them. He found a perfect correlation in the results, whereas the modified technic is easier. He considers the technic dependable and of clinical value.

**Positive Wassermann Tests in Persons with Malaria.**—Ferrando says that the Wassermann test may give nonspecific results in malarial patients. She made the Wassermann, Müller and Sachs-Vitebsky tests with the blood serum of ten non-syphilitic patients in the course of benign tertian malaria and found that the Wassermann test can give positive results during the febrile attacks of therapeutic malaria but that it becomes negative by administering quinine to the patient. The Müller test gives sustained negative results all through the course of therapeutic malaria. The Sachs-Vitebsky test gives negative results in almost all cases.

\*Pulmonary Syndrome from Malaria in Child: Case. A. Barcaglia.—p. 1011.

**Pulmonary Syndrome from Malaria.**—Barcaglia reports a case in which a child, aged 3 years, presented (coincidentally with febrile attacks of a tertian type) clinical signs of pseudo-lobar bronchopneumonia at the base of the left lung. The pulmonary syndrome completely disappeared in a few hours when fever left and reappeared with each new febrile attack. In the patient's blood, *Plasmodium vivax* was found. Antimalarial treatment resulted in complete recovery of the patient. The author reviews the literature on the pathogenesis of malarial pulmonary syndromes, previously reported. He believes that in his case an intense, intermittent and periodic congestion was produced in only one and the same pulmonary lobe. The pulmonary congestion was probably the manifestation of an anaphylactic reaction caused by the entrance of heterogenic proteins in the blood. The heterogenic proteins probably originated in a destruction of the erythrocytes or in products of the metabolism of *Plasmodium*. The author calls attention to the fact that *Plasmodium vivax* produces pulmonary syndromes which are similar to the grave pulmonary syndromes caused by *Plasmodium praecox* and *Plasmodium falciparum-quotidianum*.

Apoplexy of Uvula: Case. N. Penteado de Castro.—p. 353.  
Diagnosis of Bronchiectasis. J. Ramos Jr.—p. 357.

**Latent Jaundice.**—According to Mendonça Cortez, normal bilirubinemia exists. The normal quantity of bilirubin in the blood varies between 2 and 3 mg. for each thousand cubic centimeters of blood. Jaundice appears when the quantity of bilirubin in the blood is more than 8 mg.; when it is between 3 and 8 mg. it indicates latent jaundice. The value of latent jaundice depends on the fact that it originates in hyperhemolysis (due to infections, intoxications and spleen disturbances) and in moderate liver insufficiency. When latent jaundice but not hyperhemolysis exists, it indicates moderate liver insufficiency and contraindicates the use of any drug with a detrimental action on the liver. The diagnosis of latent jaundice is made by determining the amount of bilirubin in the blood: it occurs in various pathologic conditions. It is found in all cases of

liver cirrhosis and in diabetes but not in normal pregnancy. It may be produced by administration of certain drugs (especially arsphenamine) and by certain anesthetics (especially chloroform and ether) and may develop in alcoholism, cardiac insufficiency, certain forms of anemia, during the crises of certain infections and from internal hemorrhages and cerebral hemorrhage. The symptom is of diagnostic or prognostic value. It indicates the advisability of administering certain drugs as well as the continuation of a given treatment or surgical intervention. Constitutional hyperbilirubinemia, hepatic temperament and familial cholemia are not pathologic but abnormal conditions. From a pharmacologic point of view these patients are in the same group as those suffering from moderate insufficiency of the liver.

\*Roentgen Treatment of Case of Progressive, Multiple Myositis Ossificans. M. Sgalitzer.—p. 304.

### Treatment of Progressive Multiple Ossifying Myositis.

—Sgalitzer reports two cases of progressive multiple ossifying myositis, one of which had been observed for fourteen years and the other one for two and a half years. The latter case, in which heat application and other therapeutic measures had failed, was treated by repeated roentgen irradiations with small doses and large fields over the regions of muscular rigidity, which precedes ossification of the muscular tissues. The author reasoned that the resorption-promoting action of roentgen rays might be beneficial. The roentgen irradiations were given with 170 kilovolts, from a focus skin distance of 35 cm. and through a filter consisting of 0.5 mm. of zinc and 1 mm. of aluminum. The dosage was 150 roentgens per field. The neck was irradiated from the front, and the right half of the thorax from the front and back. The lower portion of the thoracic vertebral column and the upper portion of the lumbar cervical column also were irradiated. Three weeks later an irradiation of the entire body was given, the anterior side of the body being irradiated for fifteen minutes from a distance of 1.5 meters. This total irradiation was repeated after a month. The field irradiations were repeated at intervals of three months. So far they have been given ten times. The condition, which had been progressive for over a year and produced severe limitation of movement, improved rapidly after the first series of irradiations. The stiffness and rigidity of the muscles diminished and mobility increased, so that only a small limitation of movement remained, owing to the ossification of muscular tissues prior to the roentgen irradiation.

\*Serodiagnosis of Pemphigus. E. Urbach, S. Wolfram and R. Brandt.—p. 1479.

**Serodiagnosis of Pemphigus.**—Urbach and his associates point out that in former studies they tried to prove that the pemphigus group of disorders (pemphigus vulgaris, pemphigus vegetans and dermatitis herpetiformis Dühring) belong to the group of virus diseases. They cite animal experiments which point in this direction and, in order to produce further proof for the theory that the pemphigus group is caused by a virus, they tried to demonstrate in the blood serum of patients with pemphigus complement fixing antibodies against the supposed virus. They describe a complement fixation reaction which uses as antigen the extract of specifically infected and diseased

rabbit brains. They found this reaction positive in approximately 75 per cent of all patients with pemphigus and with dermatitis herpetiformis Duhring, whereas control serums gave a margin of error of about 4.5 per cent. In approximately 25 per cent of clinically proved cases of pemphigus and of dermatitis herpetiformis Duhring the complement fixation reaction was negative. If it remains constantly negative, it signifies an unfavorable prognosis, for it indicates that the immunity of the organism is weak. The positive seroreaction is a further proof that the pemphigus group is caused by a virus and that pemphigus vulgaris, pemphigus vegetans and dermatitis herpetiformis Duhring are of the same nature.

### Wiener Archiv für innere Medizin, Vienna

29: 161-320 (Oct. 30) 1936. Partial Index

\*Clinical Aspects and Differential Diagnosis of Syphilitic Coronary Stenosis. O. Zimmermann-Meinzinger.—p. 161.  
Pathogenesis and Clinical Aspects of Gastric Ulcer. L. Jarno.—p. 201.  
Studies on Hypophyseal Hormones of Carbohydrate and Fat Metabolism in Diabetic Patients and in Hypophyseal Tumors. M. Taubenhaus.—p. 251.

\*Presence in Cerebrospinal Fluid of Contra-Insular Hormone That Induces Hyperglycemia. W. Koch and P. Lehdorff.—p. 291.

**Syphilitic Coronary Stenosis.**—Zimmermann-Meinzinger bases his discussion of the differential diagnosis of syphilitic coronary stenosis on the clinical and necropsy observations in forty-two cases of mesoarteritis. The necropsy revealed in twenty-two cases (slightly more than 50 per cent) a syphilitic coronary stenosis. The observations indicate the greater importance of the left than of the right coronary artery for a sufficient blood perfusion of the cardiac muscle. The anamneses revealed the diagnostic importance of the stenocardiac symptoms and of dyspnea, particularly of their simultaneous appearance, of their persistence and frequently of their progressive character. The author warns against the underestimation of certain neurotic traits that occur in these patients, such as constant unrest, anxiety or excitation, because a coronary stenosis frequently exists in these patients with mesoarteritis. That the subjective difficulties are frequently of short duration and that fatalities occur occasionally in apparent health prove that a coronary stenosis may often exist for a long time without giving rise to complaints. With regard to the syphilitic factor the anamnesis was extremely unreliable, for it disclosed such a factor in only 25 per cent of the cases. Hypertension was present in a rather mild degree in only a few cases, whereas the majority of patients had normal or slightly reduced blood pressure values. A noticeable increase in blood pressure was repeatedly observed in patients with coronary stenosis, so that an increase in blood pressure cannot be cited as evidence against coronary stenosis. Failure of the action of nitrite was almost never observed, but later its efficacy became often considerably reduced or the effect was only of short duration. Strophanthin therapy frequently resulted in an increase of the anginous symptoms. Discussing the electrocardiographic aspects, the author states that in approximately 50 per cent of the patients with severe coronary stenoses the electrocardiogram taken during rest showed no pathologic changes whatever; at any rate, there were no signs indicating coronary insufficiency. The author stresses the importance of taking an electrocardiogram during an attack or at least in connection with a work test. However, he admits that even the work test may fail.

**Hyperglycemia Resulting from Injection of Cerebrospinal Fluid.**—Koch and Lehdorff review Kylin's studies on the effect of cerebrospinal fluid from normal persons and from patients with hypertension, eclampsia or diabetes mellitus on the blood sugar of rabbits. Then they describe their own investigations on this problem and show that their results differ slightly from those of Kylin. They found increased blood sugar values not only following the injection of cerebrospinal fluid from patients with hypertension but also after the injection of normal cerebrospinal fluid. To be sure, in the animals that had been given injections of cerebrospinal fluid from patients with hypertension the increase was slightly higher,

but the differences were so insignificant that they may be disregarded, and the authors are unable to corroborate Kylin's observation in this respect. However, they think that the behavior of the blood sugar of the rabbits following the injection of cerebrospinal fluid from patients with diabetes mellitus deserves attention, although it completely lacks regularity. They reason that in view of the severe regulatory disturbance of the carbohydrate metabolism, which exists in every case of diabetes mellitus, an excess as well as a deficiency of the contrainsular hormone is possible, the more so since a number of hormones of the anterior lobe of the hypophysis may exert their influence on the carbohydrate metabolism. At any rate the authors intend to continue their investigations on this problem. The cerebrospinal fluid of a patient with acromegaly resulted in an enormous increase in the blood sugar content of the test animals. Although this was to be expected, the authors admit that a single case does not justify definite conclusions. In surveying all their observations, they find that human cerebrospinal fluid usually contains a substance which induces hyperglycemia in rabbits.

### Polska Gazeta Lekarska, Lwów

15: 829-844 (Oct. 25) 1936

\*Epileptic Attacks in Chorea. A. Gelbard.—p. 829.  
Clinical Value of Electrocardiographic Dorso-Anterior (Fourth) Derivation. L. Tochowicz.—p. 832.  
Physical Therapy in Disorders of Circulation. J. Misiński.—p. 834.

**Epileptic Attacks in Chorea.**—Gelbard reports two cases of epileptic attacks in chorea during pregnancy although no attacks had occurred before the manifestation of chorea. Epileptic attacks in chorea are not rare, but pregnancy as a cause of chorea with epileptic attacks is rare and of unknown etiology. The first patient was a woman, aged 23, who had become pregnant ten weeks previously. A week before the symptoms of chorea appeared she had two epileptic attacks, six or seven days apart and after extreme excitement. The attacks caused complete loss of consciousness with general convulsions. Before the attacks a cutaneous eruption appeared in spots around the shoulders and disappeared after they subsided. As the symptoms of chorea increased, the epileptic attacks diminished and finally stopped. She had never suffered from chorea before and had had a normal childbirth two years previously. Pregnancy was interrupted by curettage and she was greatly improved after two months and returned to work. In the second case, chorea minor, the disease had progressed for three years before she entered the hospital. Recently she suffered an epileptic attack with complete unconsciousness for several minutes. This was her first attack, though she had regular fainting spells during her menstrual periods. She was the only one of her people who was not strong and healthy. She left the hospital after four weeks and has shown signs of improvement since. Both these cases are typical hyperkinesic chorea. In the first case the epileptic attack was attributed to excitement. The second was a case of Sydenham's chorea.

Roentgenologic Diagnosis, Free Fluid in Abdominal Cavity. L. W. van den Burg.—p. 2605.

**Tuberculous Burrowing Abscess in Diaphragm.**—Straub reports a case history with such an obscure course that the clinical diagnosis proved extremely difficult. The patient died and the postmortem examination clarified the main aspects of the case. Microscopic sections revealed that the peculiar burrowing abscess in the diaphragm developed from a mediastinal gland which was involved in the primary tuberculous process. A softened, caseated focus in this gland, directly adjacent to the highest point of the diaphragm, was the cause of the spreading in the diaphragm. As regards the tendency to spread in the muscle, this burrowing abscess resembles the psoas abscesses. The anatomic condition determined the spreading of the abscess in this case; the typical form made a good

drainage impossible. The author discusses some of the aspects of the case, which still remain obscure, and also the problem of the primary complex.

**Formation and Destruction of Erythrocytes.**—Meyers shows that the estimation of the number of reticulocytes in the blood is helpful in understanding the physiology of anemia. The hypothesis that all new erythrocytes appear in the peripheral circulation as reticulocytes, although not quite exact, makes it nevertheless possible to express the relation between the destruction of old and the production of new erythrocytes. In healthy persons the number of erythrocytes remains practically constant throughout life. This indicates the presence of a regulating mechanism between destruction and production. After discussing some of the factors that play a part in the formation of new blood, such as the presence of certain building materials, the oxygen tension of the blood in the bone marrow and the function of certain parts of the central nervous system, of hormones and of organs such as the spleen, the author points out that anemia develops as a result of a discrepancy between the destruction and production of blood. He takes up the various types of anemias. In five cases of anemia associated with hemolysis (increased values of indirect blood bilirubin) there was no relationship between the course of the bilirubin values and the fluctuations in the blood destruction. Consequently the blood destruction could not be alone responsible for the severe bilirubinemia, but it is likely that a disordered function of the liver did likewise play a part. A malarial infection may reduce the functional activity of the bone marrow by a direct toxin effect. If a large number of reticulocytes is found in anemia, it indicates that the formation of new blood is not deficient.

\*Anatomopathologic Investigations in Three Patients Who Died During Attacks of Asthma Together with Lethal Case of "Secretory" Asthma. J. V. Jørgensen.—p. 217.  
Normal Count in Spinal Fluid. H. Jessen.—p. 267.

**Pathology in Fatal Cases of Asthma.**—In Jørgensen's first case there were extensive changes in the lymph nodes, regarded as allergic manifestations. In the next two cases death was due to or hastened by complications regarded as allergic, conglutination of the erythrocytes in the kidneys and especially in the lungs in the one, edema of the lungs in the other. Microscopic examination showed part of the bronchi contracted and dry, another part dilated and filled with mucus, with transition stages between the two types. These phenomena are believed to be best explained by a two-phase theory. In the fourth case, with the clinical course of a "secretory" asthma, an atypical form is represented, in which one phase completely dominates and there is no expression, or only a sporadic one, of the other phase. There was simple respiratory dyspnea without the characteristic asthma stamp. The clinical experience that epinephrine is indicated early in the asthma attack further supports the conception that the attacks occur in two phases; there is no theoretical basis for the use of epinephrine in the second phase, in which it may apparently even aggravate the condition.

\*Fluorine Intoxication in Cryolite Workers. K. Roholm.—p. 981.  
\*Treatment of Some Cases of Pellagra and Polyneuritis with Stomach Preparations: Preliminary Clinical-Therapeutic Report. S. Petri and O. Wanscher.—p. 1003.

**Fluorine Intoxication in Cryolite Workers.**—Roholm says that chronic resorptive fluorine intoxication differs clinically, roentgenologically and anatomopathologically from the known sclerosing diseases of the bones. Intoxication from fluorine results from inhalation of a daily dose of from about 0.2 to 0.35 mg. of fluorine per kilogram of body weight. Examination of sixty-eight workers on cryolite exposed to the dust showed that the majority were affected. The acute symptoms are loss of weight, nausea and vomiting; the chronic symptoms, functional dyspnea, pain of rheumatic character, stiffness and constipation. The workers soon become inured to the effects. In fifty-seven (85.8 per cent) of the workers there was sclerosis of the bones of the body, as described by

Flemming, Møller and Gudjonsson, especially of the spinal column, pelvis and ribs. In some cases the mobility in the spinal column and thorax was reduced. The general condition was not disturbed. Postmortem in two workers who died from intercurrent diseases revealed no organic changes definitely attributable to the intoxication. The bones weighed up to three times the normal and were chalky white, with extensive periosteal deposits and calcification of ligaments. The bony system contained an average of about sixty times the normal amount of fluorine. The fluorine content was increased in the lungs. Evidence indicates that, when the intake of fluorine ceases, the sclerotic bony tissue is replaced by normal tissue; the ligament calcifications seem to disappear incompletely. As fluorine is eliminated in the milk, mottled teeth in the children of women workers may result if lactation is continued long.

**Treatment of Pellagra and Polyneuritis.**—Petri and Wanscher say that, after oral administration of relatively small doses of human gastric juice and preparations of swine stomach for a relatively short time in five cases of pellagra and polyneuritis, most of the symptoms were influenced, with notable improvement in two cases in which there was marked disturbance, and the deficiency or absence of a certain specific property in the stomach of the patients becomes evident.

Studies on Fat Metabolism: II. Continued Investigations on Applicability of Hemolipochrit Method and on Physiology Together with Pathology of Hyperlipemia in Different Disturbances, Particularly in Idiopathic Steatorrhea (Sprue, Nontropical Sprue, Intestinal Infantilism). B. Lawetz and P. Vogt-Møller.—p. 1009.  
\*Idiopathic Steatorrhea (Gee-Thaysen's Disease): Three Cases. E. Mogensen.—p. 1032.  
Occult Hemorrhage as Indication for Early Exploratory Laparotomy. T. Jersild.—p. 1053.  
\*Cancer Cell as Ubiquitous Variety of Normal Tissue Cells. A. Fischer.—p. 1064.  
Proctalgia Fugax (Thaysen). K. Roholm.—p. 1071.

**Idiopathic Steatorrhea.**—Mogensen reports that in his first patient, a woman aged 27, nontropical sprue in unusually pure form developed in connection with pregnancy. The second patient, a man aged 74, had spent twenty years in the tropics and had sprue after fifteen years' stay in Natal; the case is regarded as one of nontropical sprue and is the first to be reported from Natal. In addition to the steatorrhea, hyperchromatic megalocytary anemia was the dominating symptom. Treatment with diet and with liver extract parenterally resulted in marked improvement and recovery from the anemia. In a woman, aged 38, with the history of tetany for many years, the tetany depended on idiopathic steatorrhea, originated at the age of 8. In this typical case the skin disturbances were more prominent than usual. The blood sugar curve was low after both intravenous and oral administration of dextrose, which agrees with Thaysen's conception that the low blood sugar curve is not due to deficient resorption of the dextrose.

**Cancer Cell as Variety of Normal Cells.**—Fischer says that the selection theory of the origin of cancer, formulated on the basis of his own and others' observations, is strongly supported by the result of experimental investigations here presented, which show that it is possible by repeated autogenic transplantations of normal tissue in young mice to produce carcinomas in a short time. There are believed to be normally in the different organs and tissues individual tissue cells which possess all the special properties of the cancer cells. Isomorphic cells, whether, for instance, liver cells or cells of the cutaneous epithelium, have all the characteristics of liver cells or cells of the cutaneous epithelium, respectively, but nevertheless differ from the average liver or epithelial cell by a special property. That such cells do not generally develop is assumed to depend on their small number. The author asserts that this conception of the pathogenesis of cancer does not conflict with results attained by earlier experiments; it can even explain obscure points, as, for example, the hereditary factors. The apportionment and number of these cells with special properties in the tissues must be inherited. The development and realization of the cancer, as confirmed by all experimentally produced cancers, depend on various external factors, chronic irritations of different kinds, hormone factors, phenomena of age and so on.

## IMPROVEMENTS IN THE TREATMENT OF CANCER OF THE RECTUM

RICHARD B. CATTELL, M.D.

BOSTON

Within the past few years there has been definite and important progress in the management of cancer of the rectum. The fundamental principles underlying the successful treatment of this condition have long been established as regards both palliative procedures for temporary benefit and the curative or radical operations that give some encouraging prospect of relief. An understanding of the extension of cancer of the rectum beyond the primary site soon led to better results. The earlier observations, of W. Ernest Miles,<sup>1</sup> but recently reviewed by him, led to the general acceptance of the abdominoperineal resection as the ideal operation. The operation for cancer of the rectum must attempt to remove the involved rectum, an appreciable portion of bowel above and below the lesion and as wide an excision of mesentery and pelvic contents as possible. With this in mind, I strongly believe that the most radical operation should be performed which is consistent with the patient's condition and which offers a reasonable chance for survival. It is the application of this principle—utilizing the correct operation for the individual patient—that has resulted in better results during the past few years.

It is my purpose to discuss the changes in the management of these cases in recent years which has led to the successful treatment of an increasing number of patients with cancer of the rectum in order to bring these facts before the physicians who first see these patients. The discussion in this paper will be limited to carcinoma of the rectosigmoid and rectum, since the lesions in these locations properly should be considered together, because of similarity of position, blood and lymphatic circulation.

In 1934-1935, 106 patients with cancer of the rectum were treated at the Lahey Clinic, of whom I operated on 80 per cent. Dr. Frank H. Lahey and I<sup>2</sup> reported a previous series of 124 cases treated from 1928 to 1933. The experience gained from the treatment of these 230 patients will be the basis for this discussion. It must be conceded at once that the greatest prospect of cure of cancer of the rectum will follow the surgical treatment consisting of an adequately radical resection.

From the Lahey Clinic.  
Read before the Section on Surgery, General and Abdominal, at the Eighty-Seventh Annual Session of the American Medical Association, Kansas City, Mo., May 14, 1936.

1. Miles, W. E.: *Postgraduate Surgery*, New York, D. Appleton-Century Company, 1936, p. 1428; *Surg., Gynec. & Obst.* 52: 350 (Feb., No. 2A) 1931.

2. Cattell, R. B., and Lahey, F. H.: *New England J. Med.* 210: 403 (Feb. 22) 1934.

Although definite progress has been made in radiation therapy alone or in conjunction with surgery, the efficacy of this method of treatment probably cannot yet be evaluated. Since the fundamental principles underlying the correct operative treatment for cancer of the rectum have not changed, recent progress has been most evident in the modification and application of these principles. The improvement in the management of cancer of the rectum can be logically divided for discussion into four heads: (1) early diagnosis, (2) preparation of the patient for operation, (3) operation and (4) postoperative management.

### EARLY DIAGNOSIS

It is logical to assume that, with the increasing interest in the treatment of cancer of the rectum in particular, the diagnosis in patients having this condition will be accomplished earlier. A study of the cases observed and treated at the Lahey Clinic from 1923 to 1933 demonstrates clearly that this is not the case. In spite of repeated articles in the recent medical literature dealing with the early as well as with the late symptoms of this disease and with the educational measures carried out to inform the public, a large proportion of the patients who come to the surgeon for treatment have already had symptoms for nine months or more. While this does not exclude the possibility that many of these patients still have a prospect of cure, certainly the number of patients with extension beyond the local area of the bowel wall is considerably increased by this delay. If there is to be further improvement in the results from adequate treatment, it must largely result from the recognition of the earliest symptoms of the disease. It is no doubt true that the lesion is present for some weeks or even months before it produces enough symptoms to call the patient's attention to possible trouble. While it will be necessary to continue general educational measures to make the public aware of the possibility of this lesion, the most important thing at present is to be certain that the physician who first sees the patient recognizes the possibility of malignancy of the large bowel. If he is constantly aware of the frequency of the lesion, either he can carry out the necessary measures for establishing the diagnosis or he can refer the patient for these necessary examinations. A discussion of the symptoms of cancer of the rectum and rectosigmoid cannot be presented in this paper, but the steps in establishing the presence or absence of a malignant lesion in this location should be discussed briefly.

In an analysis of our total group of 525 cases of cancer of the colon and rectum, approximately 55 per cent were found in the rectosigmoid and rectum. The importance of a careful rectum examination is at once evident. A large proportion of these lesions are within

reach of the examining finger and a positive diagnosis can be established by the experienced examiner by this simple measure. In all patients with a suggestive history of this condition, the rectal examination should be followed by a visualization of the area by anoscopy, proctoscopic and sigmoidoscopic examinations. The use of the sigmoidoscope should be routine in every patient presenting bowel symptoms and is just as important as the barium sulfate enema for the demonstration of lesions in the colon above the area of the rectosigmoid. It should be emphasized that the possibility of carcinoma of the rectosigmoid is not eliminated in patients in whom anorectal disease is discovered. It is common knowledge that a considerable number of patients with carcinoma of the rectum and rectosigmoid have had recent local treatment or operation in the anorectal region. It seems evident from this brief discussion that there has been little progress in recent years in bringing a patient with carcinoma to the surgeon at an earlier time. Yet it is in this part of management of cancer of the rectum that the greatest possibility of progress is presented.

The cause of carcinoma of the rectum is, of course, unknown; yet a large amount of evidence has accumulated as to the rôle of mucosal and adenomatous polypi in the development of carcinoma of the rectum. We have had the opportunity to observe repeatedly the transition of polypi into a definite malignant condition of the rectum. The frequent occurrence of malignancy in multiple polyposis of the colon is well recognized. Multiple malignant growths of the large intestine have occurred several times in our series of cases and it is

reserve and have evidences of dehydration and anemia. The preoperative utilization of a high caloric, low residue diet and the administration of a large amount of fluids, salt solution and subcutaneous and intravenous dextrose are of great value. Blood replacement by transfusion should be carried out in the anemic patients. Measures for the relief of obstruction are extremely important, since patients with this condition do not tolerate major surgical procedures well. In the absence of complete obstruction the entire intestinal tract should be emptied by a saline purge, and barium in the colon should be removed by enemas and colon irrigations.

The importance of an adequate preoperative preparation and decompression of the colon in these patients has been emphasized by Rankin,<sup>3</sup> T. E. Jones,<sup>4</sup> Bargen,<sup>5</sup> Abel<sup>6</sup> and others. Undoubtedly, careful attention to this point has permitted a one stage operation to be performed in many patients who otherwise would have required a two stage resection. In cases in which barium has been given by mouth or as an enema, it is advisable to take a flat plate of the abdomen to make certain that the barium has been successfully removed. A long preoperative period of preparation in the hospital is probably not necessary, but sufficient time should be taken to insure getting the patient in the best condition possible before operation. The use of intraperitoneal vaccination will not be discussed, since I have had no experience with it.

OPERATION

The greatest progress in the management of cancer of the rectum in recent years has probably been made in the better selection of the type of operative procedure for the individual patient as well as in the proficiency of carrying out the elected operation. Patients with carcinoma of the rectum are frequently poor operative risks and a prohibitively high operative mortality may result if a radical abdominoperineal resection in one stage is carried out in a routine way. It must be admitted that the ideal operation for every cancer of the rectum from the standpoint of the greatest number of possible cures would be the abdominoperineal resection in one stage. At present in this country there is a decided trend toward the utilization of this operation more than any other. If this trend continues and the operation is generally utilized, there is little doubt that a high mortality will result. It is for this reason that we feel it important to sound a warning against the routine adoption of this operation. In the hands of surgeons who have had considerable experience in the operative treatment of cancer of the rectum the mortality may be kept within reasonable limits, but in the hands of a surgeon who has the opportunity of doing only an occasional operation of this type it will be safer to employ other operations.

In the group of 106 patients operated on in 1934-1935 (table 1), seventy-eight were submitted to resection, an operability rate of 73.6 per cent. Twelve (15.4 per cent) abdominoperineal resections were done in one stage (Miles operation, table 2). In the earlier series of 124 patients, sixty-six were submitted to resection, an operability rate of 53.2 per cent. In this group five one stage operations were done (7.6 per

TABLE 1.—Operability of Cancer of the Rectum

	106	100.0%	124	100.0%

a common finding to discover in the resected segment one or more rectal polypi in the rectosigmoid and rectal segments in addition to the carcinoma for which the resection was done. With the frequent use of the sigmoidoscope these polypi will be discovered at a time before they produce symptoms, and this offers a definite means of reducing the incidence of carcinoma of the rectum if they are vigorously and properly treated. It is my opinion that any polyp irrespective of size or benignancy should be immediately treated by fulguration with subsequent follow-up examinations to show that the mucosa remains smooth over this area. This definitely precludes the development of carcinoma of the rectum from that cause. The discovery of a single polyp should make one definitely suspicious that polypi may be present higher in the colon, and in all these cases the barium enema and double contrast enema should be employed.

PREPARATION OF THE PATIENT

Considerable attention has been paid in recent years to measures that will best prepare the patient for operation, and these have definitely resulted in a lower operative mortality and a lower incidence of serious complications. These measures can be roughly divided into those having to do with the general condition of the patient and with the local condition of the bowel. Many of the patients with cancer of the rectum have lost considerable weight, have a depleted glycogen

cent). It will be noted that the number of one stage abdominoperineal resections has doubled but is still applied to but one sixth of the patients submitted to resection.

There is a small group of patients with the lesion high in the rectosigmoid but too low to permit a Mikulicz resection, on whom an anterior or abdominal resection has been done as a one stage operation. In these cases a small stump of rectum is left in situ below the reconstructed pelvic peritoneum. It is possible to resect sufficient bowel below the lesion to prevent recurrence in this lower segment. We have felt it advisable to drain the presacral dead space by a drain brought out alongside the coccyx. This operation is limited to good

risk patients with a high rectosigmoid carcinoma. In our earlier series eleven (16.7 per cent) anterior resections were done, but in the latest group four (5.1 per cent) were operated on by this plan (table 2). It is in this group of cases that the one stage abdominoperineal resection has been extended. In a comparison of the two series, as seen in the table, it will be noted that decrease in the anterior resections has led to the same relative increase in one stage abdominoperineal resections.

I believe that some modification of the abdominoperineal resection in one stage should be used in a majority of these cases. The two stage operation utilized in this clinic described by Dr. Frank H. Lahey<sup>7</sup> in 1929 and later modified by me<sup>8</sup> possesses distinct advantages. The most enthusiastic proponent for the one stage abdominoperineal resection will admit that there are a considerable number of patients in whom the operation is not applicable. Patients with a lesion of borderline operability because of local extension, inflammation and possible abscess should be operated on by one of the two stage types of operation. It is my opinion that most of the patients of 55 years of age and upward go through the operation with less danger and trouble when the two stage operation is employed. In our earlier series, 50 per cent (thirty-three) of the resections were two stage abdominoperineal operations (Lahey), but during 1934 and 1935 61.5 per cent (forty-eight) were operated on by this method (table 2). The increase in the number of two stage abdominoperineal resections is due to extending the indications for operability to include less favorable cases, as shown by the increase of the operability rate from 53.2 per cent to 73.6 per cent.

There is a further group of poor risk patients that cannot reasonably withstand the radical abdominoperineal resection in either one or two stages. These patients, because of cardiovascular disease, obesity, advanced years or general debility, should be submitted to a more local type of resection, particularly if the lesion is located in the lower segment of the rectum. This operation, first described for the excision of car-

cino-ma of the rectum by Kraske and later modified by a number of surgeons, still holds a very useful place. It must, of course, be done in two stages with the first stage consisting of a double barreled or loop colostomy, the rectum subsequently being removed through a perineal incision. In 1934-1935, thirteen (16.7 per cent) posterior resections were performed. This should be contrasted with sixteen (24.2 per cent) resections of this type in the earlier series (table 2). This decrease is entirely due to the utilization of the more radical two stage abdominoperineal resection in some of the poor risk patients.

In earlier series but 30 to 50 per cent of the patients were submitted to some type of resection. There has been definite progress made in increasing the number of patients submitted to resection. In this clinic before 1930 the operability rates averaged from 50 to 55 per cent, varying but little during this entire period. With the decrease in the operative mortality, it was felt justified to submit an increasing number of patients to a radical operation that would have previously been rejected. During the last three years the operability rate has risen and remains above 70 per cent of all the patients observed. This general trend, we believe, is evidenced by the figures of D. F. Jones,<sup>9</sup> Abel,<sup>6</sup> Rankin,<sup>3</sup> T. E. Jones,<sup>4</sup> Hayden and others.

With an increase in operability above 70 per cent, it is of interest to consider the extent of the malignancy in the seventy-eight cases of resection. In six cases the lesion was adherent or invading the bladder, vagina or pelvic organs. Twelve were so extensive that no hope of cure was present and the operation was considered a palliative resection; in four of these there was perforation of the malignant process with abscess. Twenty-five patients were demonstrated to have glandular metastases. It will thus be observed that forty-three (55 per cent) were definitely in the unfavorable group.

The operative mortality in both series of cases is presented in table 3. It will be seen that the mortality remained about the same (from 13 to 15 per cent), although the operability rate was raised from 53.2 per

TABLE 3.—Operative Mortality

\* Four deaths after colostomy in resectable cases.  
† Four deaths after colostomy in resectable cases.

cent to 73.6 per cent. The total mortality in all cases considered for resection is presented, although four patients in each group died following colostomy alone. In our experience the mortality after colostomy in both operable and inoperable cases will be higher than in cases in which resection is done. The mortality after resection in the two series was 8.1 and 10.8 per cent.

The operative treatment for carcinoma of the rectosigmoid and rectum should properly be divided into palliative and curative or radical operations. There is little reason to discuss in this paper the palliative operation of colostomy in the inoperable cases of carcinoma of the rectum, since there has been no progress made. The use of radium and x-ray therapy in these cases, particularly following colostomy, has doubtless proved

7. Lahey, F. H.: Surg., Gynec. & Obst. 51: 692 (Nov.) 1930.  
8. Lahey, F. H., and Cattell, R. B.: Am. J. Surg. 27: 201 (Feb.) 1935.

9. Jones, D. F.: Ann. Surg. 94: 860 (Nov.) 1931.

of benefit in some of these patients. I feel, however, that radium and x-ray therapy should be used only in the inoperable cases and believe firmly that every patient with a carcinoma of the rectum, no matter how early, should have a radical resection. The use of radium and x-ray therapy alone and in conjunction with surgery has recently been summarized by Shedden<sup>10</sup> and Binkley.<sup>11</sup> Unquestionably, definite progress has been made, and as a better understanding of the methods and dosage is obtained by an increasing experience, they may prove of more help than they are credited with at present. Radiation therapy may increase the patient's comfort by decreasing the amount of discharge, thus relieving rectal discomfort and tenesmus, and by decreasing the size of the lesion, thus helping to relieve pain in the pelvis and in the sciatic nerve distribution.

Mention should be made of the local treatment of early carcinomatous lesions by fulguration or cauterization. Certainly this procedure is still in the trial stage, but it offers little prospect of any encouraging success. An excellent argument against local coagulation evidenced itself in a patient who recently came to the clinic because of tinnitus, with no rectal bleeding or other symptoms. During routine physical examination the digital examination revealed a small elevated area but 2 cm. in diameter on the posterior rectal wall 2 inches from the anus. On proctoscopic examination it did not appear ulcerated but bled easily on manipulation. Biopsy showed malignant adenoma. Local coagulation was considered but rejected and a one stage abdominoperineal resection was carried out. Two glands involved with metastatic growth were found in the resection specimen at some distance away in the mesentery. Radical operation offered this patient a definite chance for cure, while local excision by any means or local coagulation precluded any chance for cure. We feel that coagulation should be limited entirely to the inoperable group of cases.

By increasing the operability rate in patients with carcinoma of the rectum, it must be admitted that resections must at times be carried out in definitely unfavorable cases. Patients should not be submitted to the risk and disability of resection unless there is a reasonable prospect of their continuing to live with a fair degree of comfort for eighteen months or two years. I feel justified in resecting the primary growth in patients with early metastases to the liver if their general condition is good. In patients with local extension of the growth in the pelvis, I believe that resection should be done whenever it is technically feasible to carry out the operation. It is in this group particularly that the two stage abdominoperineal resection is applicable. As the number of unfavorable cases in which resection is done is increased, the percentage of five year cures must logically be decreased. Nevertheless the operative mortality and recurrence rate must not be the paramount factors in determining the cases in which resection should be done. The principle of giving patients the greatest number of years of comfort and usefulness should be the guiding motive here in the application of the radical removal of the growth without regard to the mortality rate, recurrence rate or ultimate death from the neoplasm.

Resection of the presacral nerve during the course of operation for carcinoma of the rectum is easily done in the unfavorable cases. This is a recent surgical

development and, I feel, has definitely contributed to the comfort of patients postoperatively, particularly those with local extension into the pelvis involving the bladder. Resection of the presacral nerve is a relatively simple procedure at the time of an abdominoperineal resection, since the entire area involved has been denuded of the peritoneum in carrying out the resection. It is suggested that this procedure be carried out as a routine in unfavorable cases, even those in which only colostomy is justified.

Definite progress has been made in anesthesia for cancer of the rectum. With an increasing experience with radical resection, the time necessary for performing the operation has been brought within the time of a satisfactory spinal anesthesia. Spinal anesthesia is now employed as a routine in all the better risks. The use of metycaine and nupercaine, the latter in dilute solutions, rather than procaine, has permitted a longer period of spinal anesthesia to be given with the same degree of safety. Ethylene or cyclopropane can be used if necessary to complete the perineal portion. The operative conditions produced by spinal anesthesia have permitted the surgeons to carry out the work under direct vision more expeditiously and more safely than under a general ether anesthesia. The poorer risk patients are advantageously operated on under a cyclopropane general anesthesia and field block of the lower abdominal wall. Better anesthesia has in these cases been a convincingly important factor in the reduction of the operative mortality.

#### POSTOPERATIVE MANAGEMENT

The immediate postoperative care of these patients aims to combat shock, prevent infection and offer general support to the patient. Transfusions should be given as a routine following the resection. The incidence of peritonitis in these cases has been markedly reduced by the two stage measures discussed earlier in the paper and is of infrequent occurrence. It may unavoidably result from a technical complication such as rupture of the growth during removal or separation of the pelvic peritoneal diaphragm during the postoperative period. Pulmonary complications, particularly postoperative pneumonia, infarct and massive pulmonary emboli, are still the major fatality factors to be overcome. In our group of patients postoperative urinary infection is very common as the result of manipulation of the urinary tract and sagging of the bladder into the hollow of the sacrum, with the resulting stasis and infection. All patients are placed on constant bladder drainage for from seven to ten days following operation to combat this. Bladder irrigation and occasional pelvic lavage by cystoscopy are necessary in many of these patients during their postoperative convalescence.

Patients operated on for cancer of the rectum should be carefully followed over a long period of time. A careful and frequent follow-up examination permits the early discovery of local recurrence at a time when further treatment may be of benefit. It is the surgeon's duty to instruct and train the patient in the management of the colostomy. Great progress has been made in this particular. By means of diet and colostomy irrigations in most cases the objectionable bag and apparatus can be discarded.<sup>12</sup> If the colostomy is managed satisfactorily, it should in no wise interfere with the patient's carrying out a useful occupation. In

10. Shedden, W. M.: *Am. J. Roentgenol.* 34: 498 (Oct.) 1935.  
11. Binkley, G. E.: *Ann. Surg.* 102: 72 (July) 1935.

12. Cattell, R. B.: *New England J. Med.* 208: 740 (April 6) 1935.

former years the management of the colostomy was left entirely to the patient's devices, was extremely unsatisfactory and resulted in much of the objections to the acceptance of a colostomy by patients.

In the presence of a recurrence, radiation therapy has a real place. The implantation of radium seeds and adequate x-ray therapy definitely increases the duration of life of these patients as well as contributes to their comfort. With persistent pelvic pain or pain in the lower extremities, the subarachnoid injection of absolute alcohol, which is a recent development, offers definite relief.

In recent years there has been an earnest effort to carry out careful follow-up studies and evaluation of results following the operative management of cancer of the rectum. This must be continued in order to evaluate properly the place of surgery in the treatment of this condition. Likewise, an analysis of the results following radiation therapy must be considered.

In considering the recent progress in the management of cancer of the rectum and rectosigmoid, what results can be expected with the use of the present method? The patient with early and favorable carcinoma of the rectum has every reasonable prospect of cure. Certainly, the results obtained by the present methods of treatment are as good as for carcinoma elsewhere in the body. In considering all patients who have been submitted to radical resection in our series of cases, 42 per cent have been free from recurrence for five years. There is little prospect of improving this figure until progress is made in the earlier recognition of this condition, so that the radical operation can be carried out at the most favorable time.

605 Commonwealth Avenue.

#### ABSTRACT OF DISCUSSION

DR. FRED W. RANKIN, Lexington, Ky.: I endorse the principles that Dr. Cattell has enunciated with the one difference that after a good many years of advocating the radical two-stage operation, I have at last joined those who believe that the one-stage combined abdominoperineal resection is preferable. The greatest advance in the treatment of cancer of the rectum during the past decade has been the preliminary preparatory period. No experienced surgeon would undertake an operation for cancer of the rectum without a period of preliminary decompression and rehabilitation. In my service this period of preliminary preparation has been extended to at least seven days and longer in the more devitalized and debilitated patients. A second change in my practice is the abandonment of preoperative intraperitoneal vaccines. So far as vaccination by a vaccine of streptococci and colon bacillus is concerned, I am convinced that my own enthusiasm did not warrant the interpretation I put on the end results. All can agree with Dr. Cattell that there is no one standardized type of procedure applicable to all cases. These cases come to the Lahey Clinic averaging a little more than nine months of symptoms, during which time the patient has known of the presence of cancer. In my series the length of time is a little longer, ten and one-half months. The patient is usually a devitalized, dehydrated individual of middle age who should be submitted to a radical operation if he can stand it, but necessarily many of these patients cannot be operated on by any one type of procedure. My average operability rate has ranged around 60 per cent. In the last eight years it has not gone below 52 per cent. About two out of three patients were subjected to resection, and that included the 10 per cent of cases presenting a movable growth that is resectable but with early metastases into the liver that Dr. Cattell spoke about. I think they should be given the benefit of a resection because a liver death is much more preferable to a death from intestinal obstruction. I found myself doing fewer of my own operations and doing more of the Miles operation while, for the group which seemed too feeble for a radical

procedure, the colostomy and posterior resection of Mummery was preferred. The principles of radical surgery should be applied to cancer of the rectum. With a more careful preparation and more meticulous technic the one-stage operation can be utilized in most cases in which the radical procedure is indicated. There is a small group of cases in which one may use the two-stage operation, either my own or Lahey's or some one else's, but I don't think that we will ever get away from the less radical operation of colostomy and posterior resection in certain cases.

DR. WILLIAM D. HAGGARD, Nashville, Tenn.: By and large throughout the country the great majority of cases of cancer of the rectum are not presented to the surgeon under a year. In cancer of the rectosigmoid about one third of the patients have acute obstruction when they are brought to the surgeon. That is the most severe indictment as far as early diagnosis is concerned. It is all important, in doing a colostomy for obstruction, to bring the cecum entirely out under a glass rod so that one can adequately handle and drain it. The second great essential is the avoidance of even an examination of the lesion itself, because it is waterlogged and reeking with micro-organisms. In enthusiasm and zeal to determine the location and type, one will literally squeeze micro-organisms into the peritoneum and cause the tremendous death rate from peritonitis. The diagnosis can be made ever so easily by a barium sulfate enema after the patient recovers from the acute obstruction. The risk of death for obstruction from cancer is rarely 50 per cent. It should have been used long before. In suspected cases of cancer of the rectosigmoid, because of changes in bowel habit, either constipation or diarrhea, or alternating, with or without blood, one should use the barium enema. In cancer of the ampulla fortunately the great majority of cases can be diagnosed by simple digital examination, which should be regularly done as an essential part of every general examination. I regret to say that medical men and surgeons do not employ it as a routine. I have had the mortifying experience of operating on a patient for other lesions, such as a goiter, and some months afterward have been chagrined to see the patient return with symptoms of carcinoma of the rectum, which was present before. In determining the curability of cancer, lymphatic extension is the deciding factor. Some recent work by Gabriel, at St. Mark's Hospital, has shown that in cancer of the rectum the extension is always upward, and that in about half of the cases the extension to the lymph glands is below the point where one divides the mesentery including the superior hemorrhoidal artery. That is encouraging. It rarely extends laterally or downward until the entire lymphatic chain is blocked. Therefore it should hearten one to think of the suggestion made by Gabriel with regard to those high lying carcinomas of the rectosigmoid that one could, in a small group of cases that might perhaps be enlarged, by early diagnosis, do a resection of the rectosigmoid area including the carcinoma and its tributary glands leaving the sphincter.

DR. RICHARD B. CATTELL, Boston: I must confess that we have been embarrassed during the past few years by the repeated questions regarding intraperitoneal vaccine. In fact most of our visitors ask "Has this patient had intraperitoneal vaccination?" We have always been hesitant to employ it and have had no experience with it because we were afraid to induce a high fever in a debilitated patient a short time before doing a major operative procedure. Dr. Rankin has performed an important service in clarifying this matter before this section. We do no sphincter-saving operations and consequently employ only one of four types of operative procedures, the one-stage abdominoperineal, the two-stage abdominoperineal, the anterior abdominal resection, and the posterior resection. Dr. Haggard brought out a very important point with regard to Dr. Rankin's figures. I am sure that most of us are in agreement with Dr. Rankin that the one-stage abdominoperineal operation is ideal, particularly in the exceptionally good risk; but the point that Dr. Haggard made was that approximately 50 per cent of Dr. Rankin's patients were operated on by the two-stage loop colostomy and posterior resection, which demonstrates clearly that Dr. Rankin agrees as to the value of the two-stage operation. I wish to say a word about colostomy. There is no way with which we are familiar that a colostomy can be constructed so as to have a satisfactory

sphincteric action. The colostomy merely provides an outlet for the intestinal flow; nevertheless I feel that the colostomy can be successfully managed; certainly in a large proportion of the cases and in all the intelligent patients, with rare exceptions, it will move only at a time when they wish it to move. This is done first by means of the diet, secondly by irrigations of the colostomy, and thirdly by doing it at the same time of day each time. If all surgeons had the opportunity of listening to the stories that these patients tell one, five, seven or eight years after operation, who are managing their colostomies successfully, they would not be hesitant in applying radical surgical principles to cancer of the rectum, which involves the formation of a permanent colostomy.

## THE BLOOD PICTURES IN THE PRIMARY DISEASES OF THE LYMPHATIC SYSTEM

### THEIR CHARACTER AND SIGNIFICANCE

B. K. WISEMAN, M.D.  
COLUMBUS, OHIO

The lymphoid structures may properly be considered as a part of the hematopoietic tissue of the body, since they contribute to the blood stream about 25 per cent of the white cells contained therein. Unlike the bone marrow, however, the lymphoid tissue has a local office to perform in addition to the general one of supplying cells to the circulation. This necessarily results in the separation of the diseases that affect the lymph nodes into two categories: those in which only a local reaction occurs and those in which the general lymphatic reaction is invoked. The latter group, often spoken of as the primary lymph node diseases, represents disorders, all of which are of unknown etiology and often of uncertain pathology, which initiate definite and often pathognomonic changes in the balance between the cells of the circulating blood. The former group, as might be anticipated, either fails to produce recognizable changes in the blood or simply reflects the usual nonspecific signs of any inflammatory reaction. The following discussion will be concerned, therefore, only with the primary lymph node diseases and the blood changes produced by them. Only those diseases susceptible to treatment with radiation will be considered.

### LYMPHATIC LEUKEMIA

Although it has long been the custom to divide lymphatic leukemia into two clinical types, acute and chronic, with aleukemic phases in each, hemocytologic experience has indicated that such a classification is neither sound nor adequate except for the grossest clinical descriptive purpose. That the fundamental change of the leukemic state may exist without any alteration whatever in the cellular content of the blood has been known since the time of Cohnheim<sup>1</sup> and can be verified wherever adequate clinical material is available. One must also recognize the fact that cases occur, commonly in older people, presenting benign sustained lymphocytoses. Another aspect of this disease in which the lymphocytosis amounts to a "low grade" or rela-

tively inactive leukemia persisting for twenty-two years has been reported<sup>2</sup> in one instance within our own experience at the department of medicine at Ohio State University College of Medicine for at least twenty-five years.<sup>3</sup> At the other extreme, it is common knowledge that the course of lymphatic leukemia may be fulminating and end fatally in a few days. Thus, from a hematologic point of view, responses of the lymphatic tissue vary to such a degree that the terms acute and chronic are inadequate to express these changes. Neither do these terms take into account the important relationship of lymphosarcoma to leukemia. Finally, there does not appear to be any justification for the term aleukemic lymphatic leukemia, since there is no fundamental pathologic difference between cases presenting low and high total white blood cell counts.

To emphasize the range of blood pictures found in this disease I shall present charts of each of the less active types. Chart 1 presents the hematologic data in a case of leukemia (the pathologic state) without a leukemic blood picture. This patient has been under observation for two and one-half years, during which time forty-eight studies of the blood have been made. At no time have there been any detectable changes in the blood from either a qualitative or a quantitative standpoint, except perhaps an occasional mild lymphocytosis. Although presenting a generalized adenopathy and moderate splenomegaly, with the lymph nodes (at biopsy) showing the histologic structure characteristic of lymphatic leukemia, his health and tolerance for work have not suffered in any detectable degree. Irradiation has been given this patient, as indicated on the chart, only for the purpose of reducing the size of the nodes.

Chart 2 is a graph of the blood studies of a case of extremely benign lymphatic leukemia that has been under our observation for over five years without any evidence of increase in the activity of the disease. Nine years preceding our contact with this patient a routine leukocyte count, performed prior to a pelvic operation, showed lymphocyte values differing very little from those present at this time. This patient, now 64 years of age, shows no clinical evidence of adenopathy or splenomegaly and, from the standpoint of symptoms, has been totally unaware of any underlying disease. No therapy, radiation or otherwise, has ever been given or needed by this patient for her lymphemia.

From the foregoing it is clear that lymphatic leukemia may be a very benign disorder which does not materially shorten life or measurably diminish health. On the other hand, it may kill quickly. It is probable that there are many more cases in the former group than one would suspect, since many are asymptomatic, do not show physical signs and hence are not seen by the physician. It is certain that practically all the latter more active types are recognized so that it is probable that one has a somewhat distorted view of the incidence of these various types and consequently of the nature of the mechanism of the disease. Certainly the clinical aspects of the former group are of the nature of a benign hyperplasia rather than of a neoplastic process. This is in conformity with cytologic and pathologic

From the Department of Medicine, Ohio State University College of Medicine.

The roentgen therapy was given under the direction of Dr. Hugh Means, roentgenologist to the University Hospital.

Because of lack of space, this article is abbreviated in THE JOURNAL. The complete article appears in the author's reprints.

Read before the section on Radiology at the Eighty-Seventh Annual Session of the American Medical Association, Kansas City, Mo., May 14, 1936.

3. F. C., seen in consultation with Dr. C. W. McGavran in 1931, died in 1935 of coronary disease at the age of 77 years. Autopsy showed only moderate glandular enlargement. The case was diagnosed by Drs. McGavran and John Musser in January 1911 from clinical and hematologic data secured at that time. This case will be reported in detail later by Dr. McGavran.

observations, which have been emphasized in a former paper.<sup>4</sup>

The effects of irradiation in this group are recognized almost universally as palliative in that it induces periods of relative symptom free remissions but does not importantly prolong life.<sup>5</sup> The objective of irradiation, therefore, at least from a hematologic point of view, is first to reduce the white blood cell count to the level that provides the most comfort to the patient and secondly to raise the level of red blood cells and hemoglobin so that the symptoms of anemia will not be present. Many patients feel a great deal better with the white count around 50,000 or even 100,000 than they do at a level of 10,000. In our clinic, therefore, irradiation is used as sparingly as possible in order to avoid making the patient radioresistant. The symptomatic complaints due to the enlargement of the lymph nodes and spleen causing pain, dyspnea, circulatory obstruction, diarrhea and the like must of course be kept under control.

As a general rule in this disease, the more inactive the case the better the results of irradiation; the more acute, the less favorable the effects. The rapidly progressive cases (acute variety) do badly. In both types, if the platelets are low, hemorrhagic phenomena are likely to be precipitated. It is therefore often necessary to support the patient with blood transfusions while therapy is being completed in order to avoid undue thrombopenia and anemia.

#### LYMPHOSARCOMA

The term lymphosarcoma is often used loosely to cover all neoplastic states of lymph nodes that are not clearly Hodgkin's disease or leukemia. Such use of the term makes for added confusion in a field in which there is confusion enough. Strictly speaking, lymphosarcoma is a disease in which there is a neoplastic transformation of the lymphocytic strain of cells. Many cases of lymph node disease cannot, of course, be accurately classified with present criteria available for recognition of the various pathologic alterations of

sional low grade lymphocytosis. Often, however, and probably usually, the neoplastic cells break over into the blood stream in greater or lesser number, producing a type of leukemia first described by Sternberg<sup>7</sup> as leukosarcoma. There are many reports in the literature in which the application of the high voltage roentgen therapy over a well localized lymphosarcoma resulted in "leukemia" (leukosarcoma), nearly always of a rapidly fatal type.<sup>8</sup> In general, the literature has not distinguished between the leukemia of this type and

Chart 2.—Blood picture in a woman, aged 64 (J. E. H.), representing a very benign type of lymphatic leukemia. Values for the white cells are plotted on a semilogarithmic scale.

that discussed in the preceding section. An analysis of this question and its significance has been published elsewhere.<sup>4</sup>

Chart 4 shows the results of a series of blood examinations made in a case of lymphosarcoma in which the tumor type of cell (in contrast to normal lymphocytes) was found in the blood stream only intermittently. This case, histologically, answered the description of the tissue described by Brill, Baehr and Rosenthal<sup>9</sup> under the term "follicular lymphoblastoma" and is the most chronic type of leukosarcoma that we have encountered. As the chart shows, the "tumor lymphocytes" or sarcoma cells are considerably more radio-sensitive than the lymphocytes. Following a single dose of 450 roentgens over the right and left inguinal lymph nodes the cells disappeared temporarily from the blood stream, although this dose did not materially affect the level of normal lymphocytes. Therapy was continued until the normal lymphocytes were markedly depressed. The chart clearly shows that the blood was nearly free from these sarcoma cells for a period of about fifty days. The behavior of these cells in response to irradiation as contrasted to the normal lymphocytes, neutrophilic leukocytes and monocytes is shown until the time of the patient's death. Uniformly, the neoplastic cells have reacted quicker and more vigorously to the destructive effects of the roentgen ray than any other cell of the blood. It has been our experience that in this type of case the cells rapidly become very resistant to radiation.

It is clear that in this type of "leukemia" radiation therapy is of little, if any, real value. With the oppor-

Chart 1.—Blood picture in pseudoleukemia (R. D. B.). Biopsy of left cervical gland, Dec. 20, 1933, showed pathologic conditions to be classic of lymphatic leukemia. At no time have the blood examinations revealed qualitative or quantitative alterations significant of lymphatic leukemia. Irradiation to the cervical, axillary and inguinal regions has been given as indicated solely for the purpose of reducing the enlargements.

this cell. In the following discussion, consideration will be given only to undoubted "true" lymphosarcoma.

From a hematologic standpoint, lymphosarcoma may show no detectable changes in the peripheral blood excepting perhaps a secondary anemia and/or an occa-

this I am in full agreement with Bunting. The most constant finding is a lymphopenia with a monocytosis giving a high monocyte-leukocyte index (over 90 per cent in our series). The total white blood cells are usually within plus or minus 10 per cent of normal limits. There is a distinct tendency to a neutrophilia, often with an absolute increase in eosinophils. A secondary anemia, chiefly of the hemoglobin type, is an almost constant feature. Given, therefore, a blood study that shows a lymphopenia with a high monocyte-lymphocyte index with normal total white blood cells, a mild neutrophilia and any increase at all in eosinophils, one would appear to be justified in suggesting the possible diagnosis of Hodgkin's disease on the basis of the blood examination alone. About 25 per cent of our cases have shown all these changes to be coexistent. I have observed no other disease, save an occasional case of tuberculosis, that gives this blood picture.

The interpretation of this cellular response in a disease of unknown etiology<sup>20</sup> assumes considerable importance and may perhaps be of considerable significance. In the first place, a mild neutrophilia with a normal

Chart 7.—Blood picture in Hodgkin's disease in a man (G. H.), aged 22, showing progressive diminution in values for all cells during the course of disease. Abbreviations under "x-ray therapy" refer to inguinal, abdominal (epigastrium) and cervical regions. Charting is on a semi-logarithmic scale.

total white blood cell count would bespeak a nonpyogenic infectious agent and may be regarded as evidence against either tumor<sup>21</sup> or virus<sup>22</sup> as the etiologic agent. The pronounced lymphopenia encountered so often with a preponderance of mature types of lymphocytes seems to indicate that the pathologic state is at least not one of lymphoid hyperplasia. Every other disease known that is associated with lymphoid hyperplasia is characterized by the appearance in the blood stream either of normal or of increased numbers of these cells, or else cells with immature characteristics. The evidence obtained from analysis of the blood lymphocytes, therefore, makes it improbable that Hodgkin's disease is a disease of the lymphocyte, even though it occurs principally in lymphoid tissue. This fact makes it appear by exclusion that the pathologic transformation occurs in the reticulum cell, free undifferentiated primitive cells or monocytes. The cytology of gland scrapings tends to implicate the monocyte and/or its primitive ancestors. Monocytes are known to form multinucleated

giant cells with ease,<sup>23</sup> whereas this activity has never been described for lymphocytes, and I have never seen it. The position that the pathologic transformation may be a neoplastic transformation of the lymphocyte is almost untenable, since it does not remotely resemble true lymphosarcoma.

The rather constant presence of a monocytosis tends to support the hypothesis that the underlying abnormality is importantly associated with this cell. This conceivably could be a result of monocytic hyperplasia and in this sense be allied to monocytic leukemia.<sup>24</sup> The monocytic increase also may be the result of a stimulus of nonspecific nature which accompanies all inflammatory reactions. On the other hand, the monocytic reaction may be of a specific nature from tuberculo-phosphate.<sup>25</sup> The presence of epithelioid cells speaks rather for the latter, and it is possible that the entire train of events occurring in this disease may be the result of or associated with activity of the tubercle bacillus, as recently advocated.<sup>25</sup> It is possible that the occurrence of eosinophils expresses the allergic state, which is such a prominent part in the immunology of tuberculosis.

Considered in its entirety, the evidence obtained from the study of the blood cells, whatever that evidence may be worth, is definitely against this being a disease in which the lymphocyte is involved, except in a secondary sense. An infectious agent, of very low virulence, of nonpyogenic origin which results in pathologic alteration and hyperplasia of the reticulum cell-monocyte maturation cycle, allied on the one hand to the tubercle bacillus or on the other hand to monocytic leukemia, would best explain the cellular reaction produced in the blood by this disease.

This etiologic interpretation of the blood picture in Hodgkin's disease is not, of course, necessarily in conflict with the fact that certain cases exhibit definite neoplastic characteristics. The frequent association of neoplasia with chronic lesions is not unknown in other tissues of the body. This phenomenon, when it arises in lymphogranulomatous alterations of lymphoid tissue, may well explain that type of Hodgkin's disease obviously neoplastic and described by Ewing as "Hodgkin's sarcoma."

#### THE BLOOD PICTURE IN HODGKIN'S DISEASE DURING AND AFTER IRRADIATION

The effects of irradiation on normal blood-forming tissues are too well known to warrant comment. The reaction in Hodgkin's disease, however, is modified by the facts concerning the nature of the blood picture and bone marrow as detailed in the foregoing section. In this disease it is clear that irradiation is started often when considerable anemia and lymphopenia preexist. It is also clear that because the pathologic tissue often extensively invades both the lymph nodes and bone marrow the available amount of functioning hematopoietic tissue may be very small. It therefore follows that very minor amounts of irradiation may produce rather profound changes in the level of red blood cells, neutrophilic leukocytes and lymphocytes. Because of these facts, irradiation in this disease must be given

cautiously and be carefully controlled by serial blood examinations. Chart 6 is illustrative of the profound effects that may result from rather light treatment. Following high voltage roentgen therapy of 350-300 roentgens given over 120 sq. cm. of skin area of the left axilla, epigastrium and right and left inguinal region over a period of fifty-five days, the red blood cells, neutrophils and lymphocytes fell from preirradiation levels of 3,000,000, 4,000 and 600 cells respectively per cubic millimeter of blood to 2,600,000, 3,000 and 180 cells. Since the counts appeared to stabilize at these levels and since the reticulocytes had not fallen (indicating no apparent damage to regeneration), a second series of treatments was given consisting of 500, 350 and 500 roentgens over 200 sq. cm. of skin area over the mediastinum, right appendiceal region and epigastrium to control persistent symptoms. These exposures were given over a period of twenty-two days. Three days following the last exposure the red blood cells, neutrophilic leukocytes and lymphocytes fell to 1,400,000, 1,100 and 200 cells respectively. The reticulocytes had dropped from 4.2 per cent to 1 per cent.

Although the patient needed further irradiation from a symptomatic standpoint, it was felt that the alarming damage to the hematopoietic tissue precluded additional therapy at this time. Serial counts were performed until the values for the blood cells showed no further rise. After establishing a plateau at levels of 2,000,000, 2,500 and 500 cells each for the red blood cells, neutrophils and lymphocytes, a single exposure of 350 roentgens over 200 sq.

cm. of skin surface in the region of the left axilla was given twenty-six days after the previous exposure. The marked fall in neutrophils and lymphocytes is clearly shown following this single exposure. It is clear that in this case only careful following of the blood changes made possible the application of radiation therapy with safety to the patient.

Chart 7 shows the effects of irradiation on the blood in another patient with Hodgkin's disease who was considerably less susceptible to the adverse influence of the roentgen ray on the blood-forming tissues. Whereas the former case developed alarming anemia and leukopenia following 2,200 roentgens over a period of five months, the present case developed very little change when approximately the same dose was given over a time interval of three and one-half months (to April 8). After continued treatment, however, the blood cell values began to fall on September 13, so that it was felt inadvisable to continue further exposures, since more damage was being done to the blood-forming tissues than was gained in relief from the symptoms of the disease. The patient died February 10 with a profound lymphopenia. The neutrophils and monocytes were the only cells to recover to preirradiation levels.

This case emphasizes the adverse effects on the erythrogenic and lymphocytogenic tissues of the combined effects of irradiation, toxemia and mechanical displacement with pathologic tissue. The advantage,

if not the actual necessity, of guiding radiation therapy with serial blood cell counts is obvious.

Chart 8 shows for a period of over five years the blood changes in a very chronic case of Hodgkin's disease. By judicious application of roentgen therapy as advocated by Craver,<sup>26</sup> the symptoms in this patient have been controlled and he has remained in a state of average good health. The blood examination on his last visit to our clinic, June 24, 1936, showed as good values for all cells as on his first visit in December 1930. I feel that the protection of his blood-forming tissues by avoiding irradiation as much as possible has helped to maintain nutrition and probably ward off infections, which are so often a problem in this disease.

Our experience would seem to indicate that careful blood counts often repeated are valuable if not actually indispensable for the patient's safety, in controlling roentgen therapy in this disease as well as in the leukemic states. Satisfactory lymphocyte and neutrophilic leukocyte values are conceded to be important in order to maintain health. Satisfactory levels of red blood cells and hemoglobin are essential for oxygenation of

Chart 8.—Blood picture in Hodgkin's disease (H. W.), showing the hematologic events in a very chronic case. Charting is on a semilogarithmic scale.

the tissues in order to maintain strength and maximum metabolic activities. It would therefore seem that the optimum in the treatment of this disease can be attained only when symptoms are controlled without unnecessary additional damage to the blood-forming tissues. This can be assured only by adding the results of careful blood examinations to the other criteria used in gaging the intensity and the time between treatments.

#### SUMMARY

1. The primary diseases of the lymphatic system that may be favorably influenced by irradiation consist of lymphosarcoma, lymphatic leukemia and Hodgkin's disease. It is probable that, excepting the benign hyperplasias, all primary diseases of the lymphoid tissues difficult to classify belong in one of these three classes.

2. All grades of lymphatic leukemia may be encountered, ranging from the pathologic state without leukemia, through benign states resembling chronic lymphocytosis, to those which are very rapidly progressive and rapidly fatal. Many of these types show very little resemblance, cytologically, clinically or histologically, to neoplasia.

3. Lymphosarcoma may be characterized hematologically either by a leukemic or by a nonleukemic blood picture. The former constitutes a type of leukemia

26. Craver, I. F.: Five Year Survival in Hodgkin's Disease, *Am. J. M. Sc.* 188: 609 (Nov.) 1934.

(leukosarcoma) which possesses special features of neoplasia and is rapidly progressive and very radiosensitive.

4. Hodgkin's disease, usually but not always, possesses a characteristic blood picture. These characteristics are interpreted as suggesting an alteration of the reticulum cell-monocyte maturation cycle arising from an infectious agent.

5. Careful blood studies in the control of radiation therapy in this group of diseases are necessary if optimum therapeutic results are to be obtained.

## ROENTGEN TREATMENT OF THE SO-CALLED MALIGNANT LYMPHOMAS

F. W. O'BRIEN, M.D.  
BOSTON

The disease entities discussed are described by their common designations Hodgkin's disease, chronic lymphatic leukemia and chronic myelogenous leukemia. Various attempts to classify them on the basis of stem cell or morphologic grounds and the merits of the controversy as to whether one or the other is an infectious process need not detain one. For all essential purposes they involve radiosensitive tissues and behave like neoplastic processes, terminating almost invariably in death.

This report covers a ten year period (1925-1935) and includes only cases that have been checked by biopsy, adequate blood studies and postmortem examination. All sections have been reviewed recently and confirmed by Dr. Frederic Parker, pathologist, and Dr. Henry Jackson of the Lymphoma Clinic of the Boston City Hospital. Any doubtful case has been discarded. Any patient who has been lost to follow up has been considered dead. Any leukemia of less than three months' duration has been considered acute and has not been included, as such is considered unamenable to any form of therapeutics. Any patient having died within one week of the beginning of roentgen therapy has been considered to have had inadequate irradiation and has not been made a part of this study. The patients comprising the statistics have had what has been considered adequate roentgen therapy, alone or in conjunction with other measures.

### HODGKIN'S DISEASE

There were forty-five patients who presented on section a characteristic histopathologic pattern of Hodgkin's disease. There were twenty-eight males, with an average age of 47.6 years; the youngest was 14 and the oldest 65 years. The youngest female was 14 and the oldest 72 years. The average age of the group was 40.6 years.

There are thirty-four dead who had their disease 14.8 months before roentgen therapy and lived 14.4 months after it, a survival average of about two and one-half years.

There are eleven living who had the disease on the average of 11.2 months before roentgen therapy and 21.7 months after, a survival of something better than two years and nine months.

The living, on the average, are living longer after irradiation than did the group that is dead. This may be due to better clinical management since the establishment of a lymphoma clinic and to the irradiation, which was begun earlier in these cases and given more aggressively.

My figures seem to bare out the contention of Minot and Isaacs<sup>1</sup> that life is not prolonged appreciably by irradiation.

Gilbert and his associates<sup>2</sup> believe that roentgen treatment in Hodgkin's disease considerably lengthens the average term of the patient's life to double or even treble from the first appearance of the symptoms. For seventeen living patients they report an average survival rate of six years and five months, but in that group are five patients, one surviving twenty years and six months, one sixteen years and ten months, one twelve years and seven months, one ten years and another nine years and five months. These total sixty-nine years and four months and in a group of seventeen cases are bound to produce a misleading survival rate.

Thirty-seven cases are classified by them as follows: acute (few weeks) one case, subacute (from a few months to two years) seven cases, average type (from 2 to 6 years) twenty-one cases, and protracted (over six years) eight cases.

More than 78 per cent by this classification are of the average and benign types living from two to six years and over. When the series I am reporting is classified similarly, 60 per cent fall into the acute and subacute types which survive two years or less, thirteen cases, or 28.8 per cent, in the average and five cases, or 11.1 per cent, in the benign types. Three of the latter patients survived a total of twenty-five years and six months and undoubtedly created an inflated survival rate (three years and eleven months) for the nineteen cases that I<sup>3</sup> reported in 1931. Of the eleven patients living in the present series, only two have lived beyond six years, one by nine months and the other by three months.

It is interesting to note that the five patients with the benign type in this series who survived the longest received low and medium voltage roentgen therapy. Each one was benefited strikingly by irradiation. When the physical set-ups employed in these earlier cases were reproduced as closely as practicable, the x-ray intensity measured in roentgens was found surprisingly close to that given now with higher voltages.

With the installation of apparatus capable of generating higher voltages, patients were treated with 165, 185 and 200 kilovolts, with appropriate copper filtration, in an attempt to carry out Desjardins'<sup>4</sup> idea of stepping up the voltage as remissions became less permanent and the lesions appeared to become "ray fast." The use of copper filtration and greater distance for medium voltages reduced the intensity much below what was obtained with the aluminum filtration and shorter distance employed in the earlier work, which may account for some of the unsatisfactory results.

For nearly three years now our technic has settled down to 200 kilovolts, 8 milliamperes, 0.5 mm. of copper, 1 mm. of aluminum, 50 cm. distance, about 210 roentgens measured in air per field, and one or two

fields daily or every other day depending on the general condition of the patient, not stopping until a well defined erythema is present, if the urgency of the symptoms warrant. The chief advantage of high voltage irradiation is that it can be used over a long period of time without damage to the patient's skin, and it has of course the added advantage over medium and low voltage of greater penetration if one is treating deep seated glandular masses. The absorbed radiation, irrespective of wavelength, seems paramount. One must not conclude, because in the literature one reads that only "weak doses" of radiation should be given in these conditions, that therefore high voltage irradiation is ill advised. Dosage is a very relative term and must be considered in relationship to voltage, current, filtration, distance, size of field, intensity measured in roentgens, duration, chronological spacing, portion of the anatomy irradiated, and the blood picture before and after treatment.

The damaging effect of x-irradiation on the red blood cells has been greatly overemphasized. It should be recalled that in Hodgkin's disease death is usually preceded by a profound anemia, irrespective of the employment of irradiation. The patients in my series who have lived the longest have had a peripheral blood picture close to normal.

I have seen no case in which anemia has developed that could be directly attributed to the irradiation. Indeed, I have seen many presenting anemia and low hemoglobin return to normal count and color index following irradiation. The explanation may lie in the fact that the irradiation, though intensive, has been fractional, applied locally, with no attempt to cover the entire body by design, the total dose per port given within a relatively short time, and the unexposed portions of the hematopoietic system not being affected, at least not directly.

The following case illustrates this rather well:

A man, aged 34, entered the hospital in December 1932 with Hodgkin's disease, which had been recognized for two years. At the time of his entrance his blood showed red blood cells 4,470,000, white blood cells 14,500, hemoglobin 72 per cent. His chief complaint was pain in the chest. A diagnostic x-ray examination demonstrated right pleural effusion. This cleared under roentgen treatment. After a remission of three months he returned with symptoms referred to his back. X-ray examination showed the lung fields clear with partial destruction of the twelfth dorsal and first lumbar vertebrae. Roentgen treatment promptly relieved the pain. No progression of the lesions in the vertebral bodies was demonstrable. Following a two months remission he returned, complaining of pain in the chest, when x-ray examination showed a tumor mass in the left lower lobe with a small amount of fluid. Roentgen therapy was instituted, followed by a remission of eleven months. In November 1934 he reported, complaining of lack of "pep." Reexamination of the chest showed the left lung field clear and a return of fluid in the right pleural space. He was again treated with high voltage x-rays. Following the last treatment of the series the roentgenologist's note Jan. 11, 1935, was "marked clearing of right lower lung field." Blood examination, February 20, was red blood cells 4,950,000, white blood cells 17,350, hemoglobin 82 per cent. That day he came to the clinic with enlarged glands in the right groin and bilateral iliac nodes, which responded rapidly to irradiation. The note on the blood under date of May 1 states that blood returned to normal; hemoglobin to 95 per cent. All this time he had been performing his duties as a police officer. Two months later paraplegia developed with sensory disturbances as high as the fourth dorsal segment. X-ray examination now showed involvement of all the lower dorsal vertebrae. He was given high voltage roentgen therapy over the dorsal spine through two oblique portals per sitting every other day for forty-five treatments, a total of 5,250 roentgens over a period

of three months. After one month of treatment sensation returned and he was able to move his toes. The amount of radiation measured in roentgens over four years was tremendous and had no appreciable effect on the red blood cells.

With local treatment there is little danger of damage to the red blood cells, especially if the long bones are not irradiated, a practice we abandoned long ago. With teleroentgenotherapy, provided the whole body is irradiated at one sitting and the intensity is too great, anemia indeed may promptly follow.

Although from statistical evidence there is no certainty that irradiation adds to the duration of life in Hodgkin's disease, nevertheless, as Jackson<sup>5</sup> has said, it is the mainstay of treatment.

The obvious direct benefits from roentgen therapy are decrease in the size of regional lymph nodes, decrease in the size of the liver and spleen with consequent relief from pressure symptoms, resorption of pleural effusion, resorption of ascites, relief of pain, restoration of sensibility and locomotion in cord and vertebral metastases, increase in red cells and color index, remissions of the disease with return to occupation, and comparative comfort over long periods of time.

#### CHRONIC LYMPHATIC LEUKEMIA

Twelve patients with chronic lymphatic leukemia were treated by x-rays, ten men and two women, all over 47 years of age. These patients had their disease on an average of 13.9 months before roentgen therapy was begun and lived an average of 14.6 months following it, a total survival of about two years and four months; 50 per cent of the group lived on an average only 3.3 months after irradiation. All of them had a marked anemia as well as an unusually high white blood cell count at the beginning of roentgen therapy. Ten are dead and two are living. The longest survival was that of a man, aged 53, who lived five years and two months, having had only low voltage therapy. Of the two living, one is a woman aged 73, living four years and five months. The last follow-up note, made December 15, one year after her last treatment, reads: "No palpable nodes, spleen and liver not felt." The other living patient is a man, aged 48, who has had his disease two years and three months. In his case the regional glands have responded to roentgen irradiation but the white blood cell count from the start has shown a steady tendency to rise. October 10, 1935, his blood was: red blood cells 4,600,000, white blood cells 221,000, hemoglobin 78 per cent.

#### CHRONIC MYELOGENOUS LEUKEMIA

There are twenty-nine patients with chronic myelogenous leukemia in the series treated by x-rays, twenty men and nine women. The majority were in the fourth decade and beyond; the average duration of the disease before treatment was 16.5 months and after treatment 21.9 months, a total survival average of 3.2 years. There are twenty-five dead, of whom seven lived for six years. There are four living, one a man, aged 41, who has had his disease about nine years; another, aged 62, who has had his disease about five years and ten months; another, aged 41, with the disease one year and nine months, and one woman, aged 34, with the disease two years and eight months.

Some of these cases were treated with irradiated blood, urine concentrates, various proprietary preparations of cod liver oil, naphthalene tetrachloride, pan-

5. Jackson, Henry, Jr.: Primary Tumors of Lymph Nodes, *Commonwealth* 21: 282, 1934.

nuclear material and solution of potassium arsenite. Blood transfusions were not used as a routine. Solution of potassium arsenite was not nearly as satisfactory in lymphatic leukemia as in the myelogenous variety. The remissions were not as prolonged in many cases as with irradiation. To argue that spontaneous remissions occur is not effective, since such is the exception and not the rule.

"In the leukemias, Fowler's solution may be tried" say Witts and Levitt<sup>6</sup> "if facilities for intelligent irradiation are not available."

Irradiation alone has any appreciable effect on the size of the spleen and adenopathy elsewhere. Harassing pruritus is allayed promptly. Iron is recommended for the anemia in leukemias. The red blood cell count and hemoglobin, however, rise quite as often with only roentgen therapy provided myelocytes and small and medium lymphocytes make up the rest of the peripheral blood picture. With myeloblasts and lymphoblasts present, the anemia is progressive and these patients do poorly.

While irradiation by x-rays remains the therapy of choice, it is empirical. In explanation of the resorption of effusion and ascites a physicochemical reaction is presumed. The reduction in size of the glands in Hodgkin's disease may be the result of fibrosis, part of the natural history of the disease, yet irradiation perhaps has stimulated the defensive mechanism of the body to bring this about. The effect most probably is not a direct one but indirect; otherwise it is difficult to explain the disappearance of glandular swellings (the so-called distant effect) outside the direct field of irradiation.

The increase in red cells and hemoglobin is quite likely, owing to physiologic stimulation of the hematopoietic system. Isaacs<sup>7</sup> is very definite that the action of irradiation in the leukemias is one of stimulation of the blood cells to divide if in the blast stage or to mature in a normal manner if of adult character.

Bovie<sup>8</sup> and others, from the analogy of the action of light on the photographic plate and the response of plants to light, cite facts, experimentally deduced, which seem to explain the reaction of the human body in its response to irradiation. In view of the contention that the effect of irradiation is one of stimulation, it is important to restate them:

1. Light produces a photochemical product, and phototropic response occurs only when the amount of this product reaches a certain minimal value.
2. The stimulative effect of illumination may be received by one portion of the body and transmitted to another. Continuity of uninjured cells is not necessary for this conducted effect.
3. Only a small amount of photochemical product is required to initiate the physiologic events through which a modification of structure is brought about.
4. Deficiency in the amount of light results in a delayed or complete failure of tissue differentiation. An exposure to an excess amount of light may result in premature differentiation.
5. Exposure to light is one of the determining conditions of tissue differentiation and, when the light intensity is reduced below the optimum, it may become the limiting factor.

These dicta appear to be particularly applicable in the group of diseases under discussion. No one more than the radiation therapist recognizes that irradiation has not accomplished what might be reasonably expected of it. For that reason many have turned to general body irradiation, which on the face of it seems a logical procedure if these diseases are widespread and systemic even before visible or palpable manifestations are present.

Evans and Leucutia<sup>9</sup> in 1927 recommended irradiation of not only the palpable glandular masses but the entire lymphatic system. Sluys<sup>10</sup> of Brussels advocated total body irradiation, using from ten to fourteen portals of entry successively over two days.

Simultaneous total body irradiation of one surface was described by Dessauer<sup>11</sup> in 1905 when he exposed the head, trunk and extremities of a patient to three x-ray tubes functioning at the same time. He had hoped to use this technic in cancer treatment, but it was not practical at the time because of the danger of absorbing large doses.

In 1927 Teschendorf<sup>12</sup> described a method of treating the leukemias with the x-ray tube placed about 6 feet (1.8 meters) away so as to irradiate a large part of one surface of the entire body at one sitting, which has come to be known as teleroentgentherapy. The anterior surface would be exposed at one time, the posterior at another and the treatments spaced according to the rate of fall of the white blood cell count.

Heublein<sup>13</sup> conceived the idea of continuous teleroentgentherapy with the tube at 18 and 24 feet from the patients. The patients received continuous roentgen therapy twenty hours a day, treatments lasting from 7.5 to 13.9 days.

There have been many modifications of teleroentgentherapy, owing to the limitations of the individual's physical set up. It is known that the irradiation of a plane surface with normal rays is uniform within a circle having the base of the normal ray as center and half the focal distance as the diameter. It is evident that technics dubbed "spray treatment" in which short distances are used are not capable of simultaneous irradiation of one surface of the entire body. It is not yet clear, of course, that such is necessary or desirable.

To cover the entire body the tube must be placed at a distance of 12 feet or more. At the Boston City Hospital a 12 foot distance is employed. With 200 kilovolts pulsating tension 5 milliamperes and 1 mm. of copper with 1 mm. of aluminum, 0.25 roentgen per minute is delivered at the center of the field.

When the distance between the center of the field and its periphery becomes greater than 2½ feet, the intensity of the field diminishes considerably. The head and the feet of the patient receive about 0.16 roentgen per minute. The treatments are spaced and 10 roentgens per surface measured at the center of the field is not exceeded.

Whether one practices continuous or spaced total teleroentgentherapy, it should be made plain that it is not something lightly to be assumed by the novice. The

entire hematopoietic system and glands of internal secretion are exposed to radiation and there appears to be a true threshold dose for each patient which cannot be exceeded without inviting violent reactions.

No one as yet has used the method over a sufficiently long period to justify its universal adoption.

#### CONCLUSIONS

1. Roentgen therapy was used locally in fractional doses in the treatment of forty-five cases of Hodgkin's disease, twelve cases of lymphatic leukemia and twenty-nine cases of mycogenous leukemia over a ten year period with symptomatic relief.

2. Some patients enjoyed relatively good health over long periods of time, but there is no convincing evidence of prolongation of life by irradiation.

3. The patients who lived longest seemed destined to do so when analyzed in the light of the natural history of their disease.

4. A method of irradiation, teleroentgentherapy, may lead to greater salvage in this group.

### LEUKEMIA OF THE STOMACH PRODUCING HYPERTROPHY OF THE GASTRIC MUCOSA

LEO G. RIGLER, M.D.

MINNEAPOLIS

Generalized leukemic infiltration of the viscera, as well as of the bones, is not uncommon. Frequently it occurs in association with a normal blood picture; i. e., an aleukemic leukemia. The blood picture may change and the characteristic signs of leukemia may appear, but during the aleukemic phase the diagnosis of the nature of the disease is unusually difficult.

Involvement of the gastro-intestinal tract by the various lymphomas—under this broad term Hodgkin's disease, lymphosarcoma, leukemia, aleukemic leukemia and reticulosis may be included—is repeatedly observed at autopsy. From a roentgenologic standpoint, lymphomatous infiltration of the gastro-intestinal tract and more especially of the stomach is of particular interest. The changes produced by this disease in the stomach and upper part of the duodenum are most intriguing because of the difficulty of their recognition during life and the bizarre picture that they present in the roentgenogram. In spite of the many cases of this type reported, there are very few on record in which the diagnosis was successfully made by means of roentgen examination. In the vast majority of the cases, the character of the infiltration was such that the roentgen examination led to a diagnosis of carcinoma rather than of lymphogranuloma.

In the case of leukemia, regardless of the leukemic or aleukemic state of the blood, two types of abnormality of the stomach may be observed on roentgen examination. In the first there is a rather localized infiltration, often near the pylorus, with a marked constriction of the lumen of the stomach. An exactly similar appearance is presented by the other lymphomas. This picture resembles that of scirrhus carcinoma; occasionally the infiltration is so bulky as to simulate a

polypoid carcinoma. Likewise lymphogranulomatous infiltration of the duodenum, as well as of other portions of the small bowel, may present a diffuse infiltrating process with stenosis and obstruction.

There is a second type of abnormality occurring with leukemia; it presents a more characteristic roentgen picture which may, perhaps, lead to a specific diagnosis. As early as 1857, Leudet<sup>1</sup> recorded the observation, at an autopsy in a case of leukemia, of a stomach in which the mucosa was elevated. Again in 1895 de Roth<sup>2</sup> called attention to this phenomenon and noted the resemblance of the rugae to the appearance of the convolutions of the brain. It has been reported from autopsies on many occasions since that time.<sup>3</sup> Both cases of chronic lymphatic leukemia, so-called pseudoleukemia, aleukemic leukemia, and even a few cases of Hodgkin's disease, have been noted as producing this remarkable enlargement of the folds of mucous membrane of the stomach. Schlagenhauser<sup>3</sup> in 1920 again likened their appearance to that of the gyri of the brain. The case reported by Ikeda,<sup>3</sup> to which I have been fortunate enough to have access, illustrates admirably the characteristic pathologic changes that are present in the stomach. Another such case, from the records of the department of pathology of the University of Minnesota, is shown in figure 1. This shows the opened stomach, removed at autopsy, in a case of chronic lymphatic leukemia. Microscopic study revealed the typical manifestations of leukemic infiltration of the gastric mucosa. Figure 1 demonstrates well the greatly enlarged, tortuous, somewhat rigid gastric rugae, which appear to be characteristic of leukemia.

A systematic report on the roentgen changes in the lymphogranulomas of the stomach was presented by Holmes, Dresser and Camp<sup>3</sup> in 1926. They stressed the difficulty encountered in making this diagnosis, but they had apparently not observed any cases of the type just described. Biggs and Elliott<sup>3</sup> had previously reported such a case with roentgen examination but the latter was not characteristic and hardly resembled the picture seen at autopsy. Their case was one of aleukemic leukemia. Ruggles and Stone,<sup>4</sup> in the course of a report of eleven cases of lymphoblastoma of the stomach, noted in the roentgenograms of some of these a close resemblance to multiple polyposis; one of their illustrations suggests, to some extent at least, the type of case discussed here. In 1933 Mead<sup>5</sup> reported a case of lymphatic leukemia in which I made the roentgen examination of the gastro-intestinal tract. The stomach presented a very bizarre appearance. It was greatly enlarged and the rugae were of tremendous size, with marked tortuosity. Similar changes were found in the duodenum. The roentgen changes were interpreted as being due to an extreme grade of hypertrophic gastritis or an unusual form of multiple polyposis. Later a

tumor mass was also found in the cecum. At operation the changes in the stomach were found to be due partially to infiltration of the gastric wall and partially to enlarged perigastric lymph nodes, which were shown to be leukemic on microscopic examination.

Since then Lüdin<sup>6</sup> has reported one case of aleukemic leukemia with this characteristic picture in the roentgenogram. The rugae of the stomach were greatly enlarged and tortuous. A biopsy, showing lymphatic

Fig. 1 (case 1).—Opened stomach removed at autopsy in a case of chronic lymphatic leukemia. Leukemic infiltration was proved microscopically. Note the greatly enlarged, tortuous rugae resembling the convolutions of the brain. Compare with figure 2.

infiltration of the lymph nodes, led to the diagnosis of leukemic infiltration of the stomach. Later the blood picture changed and presented the evidences of chronic lymphatic leukemia; at autopsy this finding was confirmed. The roentgenologic appearance was shown to be caused partially by the hyperplastic, greatly enlarged rugae, and partially by the pressure of the enlarged perigastric lymph nodes. At about the same time Koch<sup>7</sup> reported two cases with this roentgen picture in both of which the diagnosis of carcinoma of the stomach had been erroneously made. In one patient there was demonstrated at autopsy a chronic lymphatic leukemia; in the other the final diagnosis was lymphogranuloma, but the type was not stated. In 1934 Holmes<sup>8</sup> called attention to this roentgenologic appearance and suggested that it might be pathognomonic of lymphoblastomatous involvement of the stomach.

As already noted, in many instances of leukemic infiltration of the gastro-intestinal tract the blood picture may be normal. This, naturally, has made the diagnosis most difficult; any procedure, such as a roentgen examination of the stomach, which would throw light on the diagnosis, would be of distinct value. With this in mind, attention is again called to the characteristic roentgenologic appearance that leukemia of the stomach may present. The following case is reported to indicate that it may be possible to make this diagnosis even in the presence of an aleukemic state of the blood:

**CASE 1.**—A white man, aged 69, complained on admission of masses in the mouth, cheeks and neck. These had been present for two years, during which time he had become weak and tired. The past history was without significance. There were no complaints referable to the stomach.

6. Lüdin, M.: *Röntgenpraxis* 5: 816 (Nov.) 1933.

7. Koch, C. E.: *Fortschr. a. d. Geb. d. Röntgenstrahlen* 48: 271 (Sept.) 1933.

8. Holmes, G. W.: *Radiology* 23: 17 (July) 1934.

Physical examination revealed small masses in the floor of the mouth and near the tonsils. There were palpable masses under the left mandible, in both cervical, axillary and inguinal regions, of small size. The salivary glands all appeared enlarged and later there appeared some enlargement of the lacrimal glands. The skin over the neck was indurated. In addition there was a basal cell carcinoma near the outer canthus of the eye.

Examination of the blood on numerous occasions gave entirely normal results. The hemoglobin was 85 per cent; the red blood corpuscles numbered 4,960,000; the white blood cell count ranged from 7,600 to 9,000. Differential counts gave neutrophils 56 per cent, lymphocytes 38 per cent, monocytes 6 per cent. The percentages and total count varied from time to time but were substantially similar. No abnormal cells could be detected at this time. There were no other laboratory observations of significance.

Biopsies of a cervical lymph node and of the skin revealed a leukemic infiltration of characteristic type, so a diagnosis of aleukemic leukemia was made.

Roentgen therapy was applied to the enlarged lymph nodes, the salivary glands, the lacrimal glands and the skin. Treatment was also given to the basal cell carcinoma. Rapid and complete disappearance of the abnormalities ensued except for the inguinal and axillary lymph nodes, which remained palpable.

Fifteen months later the patient was again examined. At this time he complained of acid eructations. The lymph nodes were still palpable in the axillary and inguinal regions, but there were no other abnormalities.

Three years after his original admission he returned, complaining of severe pain in the epigastrium coming on shortly after the intake of food. There was a heavy feeling with much gas, and all solid food was distressing. Some loss of weight had occurred and he had severe constipation. The physical examination was essentially negative but a tentative diagnosis of carcinoma of the stomach was made and he was sent in for roentgen examination of the stomach.

Fig. 2 (case 1).—Aleukemic leukemia: Roentgenographic appearance of stomach with small amount of barium sulfate and pressure on Oct. 17, 1934. Moderate sized stomach with enormously hypertrophied rugae, which are very tortuous and irregular, is shown. Marked increase in the folds of mucous membrane throughout the stomach, even involving the distal end of the esophagus. Enormous size of the folds is shown, indicated by the arrows. Involvement of the duodenal bulb by the same type of process is shown (arrow). Compare with figure 1.

The stomach was moderately dilated and showed a remarkable enlargement of the rugae throughout (fig. 2). These were irregular and tortuous and could hardly be obliterated even with the stomach overfilled. There was marked hypertrophy of the mucosa on the lesser curvature as well as on the greater. Peristalsis, flexibility and mobility of the stomach were normal. There was a distinct enlargement of the folds of mucous mem-

brane in the distal end of the esophagus, and the duodenum showed much the same appearance as the stomach. Without any knowledge of the previous history, the following roentgenologic diagnosis was made: "Probable leukemic infiltration of the esophagus, stomach and duodenum. Possibility of extreme chronic hypertrophic gastritis to be considered."

Roentgen examination of the colon showed no abnormality. Reexamination of the stomach gave the same results.

Analysis of the gastric contents showed total acids from 59 to 86 units, free hydrochloric acid from 36 to 73 units.

The patient was put on an ulcer management for two months without relief. Gastroscoy was done but the results were indeterminate.

He was then admitted to the hospital for radiation therapy. Sixty per cent of a skin erythema dose of x-rays at 200 kilovolts was administered over the anterior gastric area and 30 per cent of a skin erythema dose was given over the posterior abdominal wall in the gastric region in three doses within twelve days. A total of 645 roentgens was administered. The leukocyte count dropped to 2,050 and the treatments were discontinued. It rose shortly to 3,750 and later to 5,900, but no further treatments to the stomach were given. He had developed, before these treatments, a considerable degree of anemia (hemoglobin 63 per cent), and this persisted.

Within two weeks there was a remarkable improvement in the gastric symptoms, and a month after the treatments the symptoms had practically disappeared. Roentgen examination of the stomach within three weeks after the treatments revealed a marked decrease in the size of the gastric rugae, and after three months (fig. 3) the picture had changed considerably. While the rugae were still somewhat above normal in size, the decrease had been most striking. The stomach as a whole was smaller and the improvement was unmistakable.

Later the axillary lymph nodes enlarged and were treated with x-rays. Gastric symptoms recurred and irradiation of the stomach was again instituted. Shortly thereafter the spleen became palpable for the first time. It was irradiated, with a prompt decrease in size. Repeated enlargements of various groups of lymph nodes occurred thereafter and the spleen became markedly enlarged. Later the liver also enlarged and the anemia became more pronounced. Blood smears at this time began to show many atypical and immature lymphocytes. The patient became weaker and died about four years after he was first admitted. Autopsy could not be obtained.

This case is of particular interest because of the characteristic roentgen picture and the typical response to roentgen therapy, which might be expected from leukemic infiltration. While the blood was normal until shortly before death, the microscopic examination of the biopsies of a lymph node and of the skin established the nature of the disease. Furthermore, the late enlargement of the spleen, the enlargement of numerous groups of lymph nodes and their characteristic response to irradiation confirmed the diagnosis of aleukemic leukemia. Certain facts should be noted in detail: The stomach was extensively and very diffusely involved but was increased rather than reduced in size. The folds of mucous membrane were greatly hypertrophied, sinuous, irregular and equally prominent on the two curvatures. Peristalsis, mobility and flexibility of the stomach wall were well preserved. What is even more significant, the first portion of the duodenum was affected in an exactly similar way, a most important sign to distinguish this lesion from carcinoma. This particular finding has been emphasized in recent reports of this condition. A comparison of figure 2 with figure 1 indicates clearly the close correlation between the roentgen signs and the gross pathologic changes of this condition. The rapid and striking response to radiation therapy, particularly the roentgen demonstration of reduction in the size of the rugae, is also confirmatory evidence of the nature of the disease. This

reaction represents here, as elsewhere in the body, an important therapeutic test for leukemic infiltration. It would seem that all these roentgen changes should be characteristic of lymphoblastomatous involvement of the stomach.

In searching for other cases of this type, a number of patients have been observed in whom extreme enlargement of the rugae of the stomach is present without any signs of leukemia, aleukemic leukemia or any other lymphomas being present. These are cases which ordinarily might be classified as chronic hypertrophied gastritis except that the enlargement of the folds of mucous membrane is far beyond that usually found and are diffuse throughout the stomach. One of

Fig. 3 (case 1)—Aleukemic leukemia: Stomach April 10, 1935, after roentgen therapy. Compare with figure 1. Note striking decrease in size of gastric rugae and general change in mucosal markings, indicating effects of irradiation on leukemic hyperplasia of rugae.

these cases is detailed here to indicate its resemblance to the case of aleukemic leukemia previously described and to bring out certain differences:

**CASE 2.**—A white man, aged 36, complained of severe pain in the epigastrium increasing for one year. The pain was worse after heavy meals or hard work. There was nausea, no vomiting, no qualitative food distress, and no relief from food or medication. The appetite was normal and there was a slight loss of weight. An appendectomy had been performed four years before and he had had a hernia for one year.

The physical examination was entirely negative except for the evidences of a right indirect inguinal hernia. Slightly palpable inguinal nodes were found but were not more prominent than usual. No other enlarged lymph nodes were found and the spleen was never palpable.

Roentgen examination of the stomach with a barium sulfate meal was done. The stomach was normal in size but showed a generalized striking increase in the size of the gastric rugae (fig. 4). These were sinuous and not readily compressed. Mobility and flexibility of the stomach were normal, while the peristaltic activity was increased throughout the stomach. The first portion of the duodenum showed also a marked hypertrophy of the mucosa, the appearance simulating that in the stomach. No evidence of ulcer or tumor was obtained. The roentgenologic diagnosis was "chronic hypertrophic gastritis and duodenitis of marked degree. Possibility of leukemic infiltration must be considered."

Cholecystography revealed a normally functioning gallbladder. Reexamination of the stomach produced the same results.

Repeated studies of the blood were made. The hemoglobin ranged from 90 to 100 per cent. The red blood cell count was 4,900,000. The count of white blood cells ranged from 8,800 to 11,900, being persistently slightly higher than normal. Neutrophils ranged from 57 to 71 per cent; lymphocytes ranged from 22 to 36 per cent. The eosinophils were constantly increased above the normal, ranging from 3 to 13 per cent. There were no immature or abnormal cells.

Analysis of the gastric contents gave total acids from 12 to 41 units, free hydrochloric acid from 8 to 32 units. All other laboratory tests were negative.

He was placed on bed rest and a restricted diet regimen for five weeks without any particular relief or any change in the roentgen signs.

Irradiation of the stomach was proposed with two possibilities in mind. If this was a case of aleukemic leukemia with leukemic infiltration of the stomach, a rapid and favorable response might be expected. It was also considered possible that the lymphocytic infiltration that occurs in chronic hypertrophic gastritis might be favorably affected by irradiation. Accordingly he was given a moderate dosage of x-rays at 200 kilovolts, 90 per cent of a skin erythema dose being applied over the anterior wall of the abdomen in the stomach area in

been any enlargement of the spleen or any of the remaining lymphatic apparatus. What is even more significant is the signal failure of response to radiation therapy. There was no relief of symptoms and no diminution in the size of the mucous membrane folds.

It seems evident that this picture of marked enlargement of the rugae of the stomach is not entirely pathognomonic of lymphoblastomatous infiltration but when encountered should arouse suspicion of this condition in every instance. Differentiation from non-malignant hypertrophy of the gastric mucosa may possibly be made by means of a therapeutic test with irradiation. The rapid and favorable response of the leukemic case is in sharp contrast to the failure of irradiation in the simple hypertrophic gastritis.

#### SUMMARY

1. Leukemic infiltration of the stomach may produce a striking picture of enormously enlarged gastric rugae resembling the convolutions of the brain. Involvement of the duodenum is usually found.

2. Radiation therapy will cause a marked reduction in the size of these folds and a corresponding improvement in the gastric symptoms presented by the patient.

3. The roentgen signs in the stomach may be obtained regardless of whether or not blood changes are present.

4. Other lymphogranulomas may possibly produce a similar appearance.

5. Chronic hypertrophic gastritis of extreme grade may simulate these roentgen appearances. Radiation therapy may possibly serve as a therapeutic test, as it does not appear to produce any change in the symptoms or roentgen signs in these cases.

#### ABSTRACT OF DISCUSSION

ON PAPERS OF DRS. WISEMAN, O'BRIEN AND RIGLER

DR. ROSS GOLDEN, New York: Dr. Rigler is quite right in saying that this leukemic infiltration may be simulated by other forms of this group of diseases. I have had at least four cases in which the pathologists made a diagnosis of lymphosarcoma and the roentgen picture could easily be confused with what he has shown. Martin described a helpful point, that the involvement in so-called lymphoblastoma of the stomach may be multiple; that is, of the fundus and also of the pyloric part or the simultaneous involvement of the duodenum and the stomach. He also pointed out the exaggeration of the mucosal folds. However, exaggeration of the mucosal folds may be present in other conditions. In a number of instances when a neoplasm, not typical of carcinoma, was present with exaggeration of the mucosal folds, the possibility of lymphoblastoma has been suggested only to have the biopsy disclose carcinoma. Unless the duodenum is involved, the diagnosis of lymphoblastoma of the stomach is very difficult and is likely to be wrong. A very important step is to think of the possibility of the disease. The attempt to diagnose it is well worth while because of the very satisfactory response to radiotherapy. One patient, an employee of the hospital, is now alive and well four years after operation for a perforated lymphoblastoma of the stomach. Dr. O'Brien repeated the statement frequently encountered in the literature that roentgen therapy probably prolongs but slightly, if at all, the life of the patient, although it may greatly improve his physical condition. This statement, to which I am unable to subscribe, seems to me to deserve further and much more critical analysis. The site of onset of Hodgkin's disease may be roughly classified under four headings: first, and probably the most common, is the peripheral lymph nodes; second, the chest, usually the mediastinum; third, the abdomen, often the gastro-intestinal tract, and, fourth, the osseous system. The last is quite uncommon in my experience, although I have seen two or three cases of it. This disease

Fig. 4 (case 2).—Chronic hypertrophic gastritis without evidence of leukemia. Note markedly enlarged rugae of stomach (arrows) and similar involvement at base of duodenal bulb (left arrow). Note how this picture resembles that of previous case shown in figure 1.

three treatments over a period of twenty-four days. A total of 645 roentgens was given. Two months later 860 roentgens was given in much the same manner.

There was little or no response to this treatment. The blood remained about the same; the symptoms were not affected after the first reaction to the irradiation had been overcome. Reexamination of the stomach with the barium sulfate meal showed no appreciable change. The patient has been followed for eighteen months and numerous forms of treatment have been instituted without success.

The roentgen signs remain about the same.

Gastroscopy was recently attempted but was unsuccessful because of inability to pass the tube.

The roentgen appearance in this case is similar to those previously discussed. The rugae of the stomach are greatly enlarged, tortuous and irregular; the changes in the duodenum are similar. The intensive studies of the blood and the physical examination, however, have revealed no evidence whatever to suggest the presence of leukemia. Obviously, the latter cannot be entirely excluded without long continued observation, but during a period of eighteen months there has never

may kill a patient early in its course by interfering with some vital function, such as respiration, by producing tracheal compression. Roentgen therapy, if properly applied, may for years prevent tracheal compression, intestinal obstruction, perforation of a viscus, and a number of other complications that may result in very early death of the patient. Obviously, peripheral lymph node involvement offers no immediate threat to life. If the patients live long enough, the disease almost invariably becomes generalized; bones and the abdominal lymph nodes, as well as peripheral lymph nodes, may be involved, and at the end it is sometimes hard to tell just what the mechanism of death may be. I should like to see such a series of cases analyzed from the standpoint of the site of onset. I believe that would give a different picture of the part played by roentgen therapy in Hodgkin's disease.

DR. ISRAEL DAVIDSOHN, Chicago: I should like to emphasize the remarks Dr. Wiseman made with regard to the necessity of a more careful study of the morphologic features of the blood. He is right when he demands that the finer phases of the examination of diagnostic importance should be carried out by an expert. However, I wish to take issue with his remark in which he stated that the blood count should not be done by the technician. I hope he will elaborate on that point, because I am afraid that soon some of my colleagues will be told that they should not have their technicians do any more blood counts. That might create a difficult situation. I hope that Dr. Wiseman will agree with me that the quantitative part of the count can be done by a good technician, but I agree that for details of the morphologic study of the blood smear the expert must be responsible, particularly in complicated cases. I should like Dr. Wiseman's opinion on blood examination in mycosis fungoides, which is of considerable interest to radiologists. I have seen cases in which the blood examination gave results indistinguishable from those commonly seen in Hodgkin's disease.

DR. B. K. WISEMAN, Columbus, Ohio: Examination of the blood is one of the oldest of laboratory methods for obtaining facts concerning disease. It is also one of the youngest. The older technics, in which use was made of fixed, stained and therefore necessarily dead cells, continues to be a valuable method for the study of blood cells. However, the recent advances that have been made, particularly by the Sabin school, in which living cells stained with vital dyes are utilized, has added so much to our concepts relating to the pathologic physiology of blood formation that no hematologist today can disregard this newer hematology. With the addition of this most important refinement to cytologic study, hematology has evolved from a laboratory procedure dominated largely by technicians to a science requiring the efforts of the most skilled and highly trained cytologists. Experience has convinced me that blood "counts" executed in the time honored way well deserve the disapprobation so often accorded them by clinicians and must be replaced by adequate examinations in which technical methods are executed by physicians possessing adequate comprehension of the cytology of blood cells and the basic principles of the physiology and pathology of the blood-forming tissues. Failing in this, much if not most of the value in interpretation of the changes in the blood will be lost. Due recognition is accorded the fact that the conditions as outlined cannot as yet be met generally; nevertheless, this objective is not impossible to attain if its importance is fully recognized. These remarks refer, of course, only to the critical examination of the blood cells; mechanical procedures, including total counts, reticulocyte and platelet counts and hemoglobin estimations, properly belong in the domain of the technicians. Relative to the blood observations in mycosis fungoides, I am compelled to evade a direct answer to this question on the ground that identification of this clinical state is uncertain when reference is made to a clear-cut pathologic lesion. I recall two cases presenting the pathology of the skin lesion resembling Hodgkin's granuloma, in which a blood picture was obtained similar to that of systemic Hodgkin's disease. Other cases with indefinite pathologic appearance showed a blood picture correspondingly not characteristic of any particular disease syndrome.

DR. F. W. O'BRIEN, Boston: I think that Dr. Golden's point is well taken, and when I talk about survival rate of course I do not mean that roentgen irradiation is not a life-saving

measure. I think it is something more than the palliation gesture to which Dr. Wiseman refers. Quite as much is done with it as with any of the chronic kidney diseases or chronic heart diseases, but considering the natural history of these diseases, some patients are destined to live a long time. One case in the Boston City Hospital I have followed for twenty-six years, and three biopsies have been made. Another patient, operated on fourteen years ago, is living after seventeen years. Neither has had any kind of roentgen irradiation. I am sure that if we had treated them we would have felt, as Gilbert and his associates do, that the disease had gone through a stage of evolution, as he describes it. It comes back again to the point Dr. Golden made, that the site of the disease has a great deal to do with the prognosis, and if we ever get a large enough group of cases I hope to analyze the group according to that idea.

## THE SURGICAL RELIEF OF IMPOTENCE

FURTHER EXPERIENCES WITH A NEW  
OPERATIVE PROCEDURE

OSWALD S. LOWSLEY, M.D.

AND

JAMES L. BRAY, M.D.

NEW YORK

The value of an operative procedure is determined only by the results obtained and the permanence of these results. This is especially true in an operation that has been designed for the cure of impotence. Immediate results are often misleading, and it is only by experience with many patients for a long period of time that one is able to choose the type of case suitable for the operation, to modify the operative technic if necessary, and last, but not least, to state with a fair amount of accuracy the result that will be obtained.

About one year and nine months has elapsed since the first patient was operated on for the relief of impotence by a new method developed by the senior author. The operation was first performed in the Department of Experimental Surgery<sup>1</sup> at the New York Hospital.

The first patient operated on has shown no reduction in his sexual competence, and the other patients successfully operated on have remained cured.

The present communication is not concerned with impotence due to syphilis, cerebrospinal lesions or glandular deficiency but with sexual inefficiency resulting from (1) traumatism of the perineum following an external blow or surgical operation, (2) inflammatory lesions of the perineum resulting in extensive scar formation, (3) lack of muscle tone, and (4) advancing age. Our particular concern is with the first, third and fourth groups—those who are impotent because of traumatism to the perineum and the older group of men, who have ample libido, normal testicles and hence normal secretion of the sex hormones, and no interference with the nervous tracts involved in the sexual act, but who cannot have erections because of failure of the physiologic activities of this part of their anatomic structure.

Much experimental work has been done in an endeavor to relieve impotence in the many whose libido is unimpaired but whose sexual efficiency is diminished or absent.

Owing to lack of space, this article is abbreviated in *THE JOURNAL*. The complete article appears in the reprints, a copy of which will be sent by the authors on receipt of a stamped addressed envelope.

1. The authors are indebted to Profs. George Heuer and Joshua Sweet for their cooperation in the conduct of the animal tests necessary for these experiments.

OPERATIVE AND NONOPERATIVE TREATMENT  
OF IMPOTENCE

Treatment of impotence may be divided into general and local. Surgical treatment, with which we are here primarily concerned, is of course a local measure. General measures are chiefly medical and physical therapeutic.

In some cases of organic impotence—for example, those due to induration of the penis—operation has

Later he conceived the idea of grafting slices of human testicle, taken from a living or recently dead subject, between the layers of the rectus muscle. The testicle to be implanted was cut into slices from 1 to 2 cm. thick; these were denuded of the tunica albuginea and placed in a bed previously prepared for them in the rectus muscle. The muscle sheath was sewed with catgut and the skin with silkworm gut. In most cases the transplants absorbed within a few months, and the potency of the individual declined to its former state. Those cases in which the operation appeared to have accomplished its purpose were probably instances of psychic impotence, with no actual loss of sexual power. The operation had a very limited application owing to the difficulty of procuring material for grafting. Occasionally men were found with a functioning testicle in the scrotum and an ectopic testicle in the inguinal canal or elsewhere, requiring surgical removal and with which they were willing to part for a substantial consideration. In still rarer instances the testicles of suicides and of executed criminals would be available.

Stanley<sup>6</sup> of California produced the same result by injecting sterile particles of sheep's testicles with wide bore needles.

With the idea of conserving the internal secretions essential to virility, some surgeons have tied off the vas deferens. This was done several generations ago in

Fig. 1.—Operation for impotence: 1. Skin incision with sound in urethra. 2. Incising and freeing Colles' fascia over bulb. 3. Freeing Colles' fascia laterally over ischio-cavernosus muscle. 4. Freeing Colles' fascia posteriorly. 5. Left ischio-cavernosus muscle held up, showing relaxed condition of muscle.

often proved worse than useless, so that palliative treatment is resorted to even in cases apparently well suited to surgery.

The theory underlying ligation of the dorsal vein is similar to that on which are constructed the mechanical devices obtainable for assisting erection. These function by compressing the veins and preventing their too rapid emptying, thus maintaining the penis in a turgid state. As Wooten<sup>4</sup> explains it:

In atonic impotence there is a loss of tonicity in all of the tissues, and a relaxed dilated condition of the veins and sinuses. The ligation of the dorsal vein cuts off the main exit of venous blood and collateral circulation eventually takes its place.

Transplantation of the testicle, advocated by Lespinasse<sup>5</sup> nearly twenty years ago, received wide newspaper publicity and was generally referred to as the "monkey gland operation" or "rejuvenation." Lespinasse himself made no such fantastic claims. Believing that most cases of impotence were due to failure of internal secretions, he at first attempted to correct this, in men young enough to have active endocrine glands, by the administration of glandular extracts.

Fig. 2.—Operation for impotence: 1. Anatomy of perineum; muscle of perineum involved in plication procedure; method of placing plication sutures. 2. an attempt to reduce prostatic hypertrophy. Hirsch's<sup>7</sup> comment on this procedure was as follows:

Let us grant that blockage of the vas will increase the vital secretions produced by the cells of Leydig. Can we picture such substances remaking new penile arteries; or causing the calcium deposits within the vessel walls to absorb; or dissolving

the scar tissue which has replaced the intima of the helicine arteries? The urologist cannot remake tissue. Some cases are beyond his aid; others he can improve; and some he can return to a normal condition. No one has ever been able to make young tissue out of old tissue, and the urologist should not be expected to accomplish the impossible.

Ligature of the vas is, of course, the much publicized Steinach operation. The idea did not originate with Steinach but was proposed in 1903 by the French

Fig. 3.—Operation for impotence: 1. Piece of ribbon gut, threaded on needle to be used in plication. 2. Method of placing the ribbon gut plication sutures in the bulbocavernosus and the ischiocavernosus muscles. 3. Shortening effect caused by plication suture in left ischiocavernosus muscle. 4. Plication sutures placed in right and left ischiocavernosus muscles and the tightening effect produced by placing plication suture in bulbocavernosus muscle.

scientists Ancel and Bouin, who noted that ligation of the vas in some of their experimental animals greatly enhanced sexual desire and that the interstitial cells of the testicle increased in number at the expense of the cells concerned in spermatogenesis. This suggested that shutting off the avenues of sperm formation would heighten production of the secretion especially concerned with sex desire; that is, the sex hormone as distinguished from the seminal fluid. Steinach carried his experiments much further and reported some wonderful returns of sexual power in bulls, in rams and later in human beings. Many, both here and abroad, followed his teachings.

Because ligation of the vas sometimes causes formation of a spermatocele, Sand and Tournade proposed a partial epididymectomy instead of the vas ligation. Several centimeters of the upper part of the epididymis was freed from the testicle proper without injuring the blood vessels, and the freed portion was resected between ligatures.

Comment is unnecessary regarding the advisability of employing the previously mentioned mechanical contrivances for encouraging and maintaining erection, or splinting a flaccid penis so that intromission might be accomplished in the absence of erection.

Huhner<sup>8</sup> has devoted a great deal of study to the relation of chronic inflammation and pathologic changes

in the prostatic urethra to sexual inefficiency and considers local treatment of the verumontanum, by irrigations and instillations, all important. Other authors have reported good results from treatment directed to the verumontanum.

For many years one of us has used subcutaneous injections of a specially prepared alcohol extract of gonads, adrenal and anterior pituitary in an attempt to boost the internal secretions of the patient, with many favorable responses.

Diathermy and hydrotherapy likewise have their ardent advocates. However, those who have obtained the best results through employment of these measures are unable to tell precisely whether the treatment actually did good of itself or was merely instrumental in changing the patient's psychic outlook. Wallace<sup>9</sup> found that a number of his "psychic cases" had four plus Wassermann reactions and that vigorous anti-syphilitic treatment resulted in complete recovery of some of the younger patients. In cases in which tertiary effects had caused definite nerve injury, no help was possible.

Perusal of the literature leads to the impression that the views of physicians and surgeons remain unchanged despite the introduction of new methods and advances

Fig. 4.—Operation for impotence: 1. All plication sutures placed and tied; shows the result produced by sutures. 2. Final skin closure.

in glandular therapy. The curable cases are largely psychic and dependent on some functional disturbance caused usually by masturbation or excessive sexual intercourse. That a few cases are curable by surgery seems well established; but the patients must be skillfully selected and operated on only after all palliative means have been exhausted.

ANATOMICOPHYSIOLOGIC PROCESSES INVOLVED  
IN ERECTION

Regarding the anatomicophysiologic processes involved in the production of erection, Howell<sup>10</sup> says:

During this act [erection] the penis becomes hard and erect, owing to an engorgement with blood. The structure of the corpora cavernosa and corpus spongiosum is adapted to the function, being composed of relatively large spaces enclosed in trabeculae of connective and plain muscle tissue—the so-called erectile tissue. . . . Eckhard demonstrated the essential facts in the process. This investigator discovered that in the dog stimulation of the nervi erigentes causes erection. These nerves are composed of autonomic fibers arising from the sacral portion of the spinal cord. They arise from the sacral spine nerves, first to third [dog] on each side, and help to form the pelvic plexus. They contain vasodilator fibers to the penis, as well as to the rectum and anus, and also visceromotor fibers to the descending colon, rectum, and anus.

Eckhard,<sup>11</sup> Lovén<sup>12</sup> and others have shown that when these fibers are stimulated there is a large dilatation of the arterioles

Fig. 5.—Operation for impotence: 1. Skin incision 4 cm. in length over suspensory ligament. 2. Shows blunt freeing of suspensory ligament laterally. 3. Placing ribbon gut suture to constrict suspensory ligament around vessels. 4. Ribbon gut suture tied, compressing dorsal veins. 5. Final skin closure.

in the erectile tissue of the penis and a greatly augmented blood flow to the organ. If the erectile tissue is cut or the dorsal vein is opened, the blood flow under usual conditions is a slow stream, but when the nervus erigens is stimulated the outflow is very greatly increased; according to Eckhard's measurements, eight to fifteen times more blood flows out of the organ. The act of erection is therefore due essentially to a vascular dilatation of the small arteries whereby the cavernous spaces become filled with blood under considerable pressure. The cavernous tissues are distended to the limits permitted by their tough fibrous wall. It seems probable that the turgidity or rigidity of the congested organ is completed by a partial occlusion of the venous outflow, which is effected by a compression of the efferent vein by means of the extrinsic muscles (ischiocavernosus and bulbocavernosus) and possibly by the intrinsic musculature as well. This compression does not occlude the blood flow completely, but serves to increase greatly the venous pressure.

10. Howell, W. H.: A Textbook of Physiology, ed. 12, Philadelphia, W. B. Saunders Company, 1933, pp. 1073-1074.

11. Eckhard: Untersuchungen über d. Erektion d. Penis beim Hunde, Beitr. z. Anat. u. Physiol. 3, 1863.

12. Lovén: Berichte über d. Verhandl. d. Königl. Sachs. Gesell. z. Leipzig, 8, 1866.

This explanation of the act of erection, while no doubt correct so far as it goes, leaves undetermined the means by which the dilatation of the small arteries is produced. Vasodilator nerve fibers in general are assumed to produce a dilatation by inhibiting the peripheral tonicity of the arterial walls. If this explanation is applied to the case under consideration, it forces us to believe that throughout life, except for the very occasional acts of erection, the arteries in the penis are kept in a constant condition of active tone. Moreover, on this view we should expect that section of the vasoconstrictor fibers to the penis, by abolishing the tone of the arteries, would also cause erection. These constrictor fibers arise from the second to fifth lumbar spinal nerves, and reach the organ by way of the hypogastric nerve and plexus and the pudic nerve. No such result of their section is reported, and it seems that in the matter of erection the actual mechanism of the great dilatation caused by the nervi erigentes still contains some points that need investigation.

Marshall<sup>13</sup> says, in this connection:

The erection of the penis is brought about partly through the contraction of the ischiocavernosus (or erector penis) and bulbocavernosus muscles, certain of the fibers of which pass over the efferent vessels and so arrest the outward flow of blood. The result of this contraction is that whereas the blood can freely enter the dilated vascular spaces of the penis, its exit is retarded, while this leads to a further distention of the vessels, the venous outlets of which became still more compressed. Although the muscular penis mechanism unquestionably assists in the erection of the penis, it is equally clear that it is incapable by itself of causing that phenomenon, since erection can be induced by ligating the efferent veins. Moreover, the penis can be made to erect in animals in which the muscular mechanism has been paralyzed by the injection of curare, but the erection in such cases is incomplete.

Frank Hinman,<sup>14</sup> writing on the subject of priapism, agrees substantially with this opinion:

To this increased inflow in an erection is opposed a partial occlusion of the venous outflow. The efferent veins of the corpora cavernosa pass by way of each crus through the ischiocavernosus muscle, and that of the corpus spongiosum by way of the bulb through the bulbocavernosus muscle. The dorsal vein of the penis is the efferent outlet for the glans and has no constricting muscle other than intrinsic ones. These muscles are supplied by the pudic nerves and their contraction completes the act of erection by compression of these efferent veins which they surround, the occlusion not being complete, but enough to greatly increase the venous pressure in the erectile tissues. In addition to these special muscles there are smooth muscle fibers freely distributed throughout the spongy tissues of the penis, action of which, no doubt, has an intrinsic value in increasing venous pressure.

Henderson and Roepke<sup>15</sup> suggest that skeletal ischio-cavernosus muscular contractions may play some minor part in erection of the penis.

Crawford and George,<sup>16</sup> in a series of experiments on dogs conducted with testicular injections, arrive at the conclusion that "1. There seems to be in the testes a specific dilator for the penis. 2. Agents which dilate the blood vessels of the hind limb increase to some extent the volume of the penis."

Carl J. Wiggers<sup>17</sup> expresses the opinion that the increased rigidity is due to the flooding of the cavernous spaces with blood as a result of the dilatation of their afferent arterioles. Compression of external veins by skeletal muscle contraction does not occur. He believes that secondarily the venous outflow from the efferent veins may be impeded, however, owing to compression from within against the rigid outer coat. Erection,

which occurs coincidentally, is not due to muscular action but is produced through a mechanical leverage action of the suspensory ligaments attached to the posterior portion of the cavernous tissue.

Samson Wright<sup>18</sup> does not mention the rôle of the ischiocavernosus or the bulbocavernosus muscles in connection with the causation of erection, nor does C. Lovatt Evans<sup>19</sup> in his revised edition of Starling's Principles of Human Physiology.

It is apparent, from a review of the literature, that later writers are less certain of the rôle of the ischiocavernosus and bulbocavernosus muscles in the production of erections. Our experimental work indicates that they are of great importance, but further experimentation must be done before definite conclusions can be drawn.

#### ANIMAL EXPERIMENTS

A series of animals was subjected to the operation which was later utilized in human beings for the purpose of determining whether ribbon gut gave the best results and whether tightening of the ischiocavernosus muscle on each side and the bulbocavernosus muscle increase the tendency toward erection. It was found that ribbon gut was successful in all cases tried and that ordinary catgut sutures were entirely unsuccessful for this purpose, the latter causing necrosis and defeating the purpose of the operation.

#### HUMAN CASES

The results on animals were so striking that a series of men were operated on with the following technic: The anesthesia may be either spinal or sacral.

The patient is placed on the operating table in an exaggerated lithotomy position, and a No. 20 French sound is passed into the urethra. An incision is made over the bulging part of the perineum, extending in the midline from a point about 10 cm. from the anal margin down toward that structure for about 5 cm. A branch is then made laterally on each side to a point just above the attachment of the crus penis, the completed incision resembling an inverted Y. The incision is deepened through fat and areolar tissue until the corpus spongiosum, surrounded by the bulbocavernosus, and the crus penis (corpus cavernosum) on each side, surrounded by the ischiocavernosus, are exposed.

Chronic ribbon gut, studded with an atraumatic needle, is inserted into the lateral edge of the muscularis bulbocavernosus, pulled across the belly of the muscle and passed through the other side, with just sufficient strain to plicate the muscle and produce the exact amount of pressure to reinforce any contraction necessary to aid in producing an erection. Two other similar stitches may be necessary to tighten the whole muscle. A figure-of-eight ribbon gut suture is inserted into the ischiocavernosus muscle on each side, care being taken not to injure or unduly compress the fairly numerous nerves and blood vessels in this area. By tightening the suture a reef is taken in the muscle, thus shortening it by approximately 1 inch (2.5 cm.). The wound is closed in layers without drainage.

#### MODIFICATION OF THE OPERATION

Owing to the fact that a few patients, three in number, were relieved of their impotence for a short time and then began to show deficiency again, it was discovered that the dorsal veins of the penis had widened, allowing the extensive collateral circulation to interfere

seriously with the stasis necessary for the production and maintenance of erection.

It was therefore decided to interfere with the collateral circulation on the dorsum of the organ. This was accomplished by inserting a ribbon gut ligature through each leaf of the suspensory ligament, and when this ligature is tied, compression is made on the vessels draining the dorsum of the penis, thus aiding in the necessary stasis instead of being a detriment to it.

This modification was so successful in relieving the three cases involved that it has now been adopted and utilized in every case.

A brief summary of the thirty-three cases in which operation was done is presented in the accompanying table.

#### TYPES OF CASES IN WHICH OPERATION SHOULD NOT BE DONE

It has been found that the muscles of men over 60 years of age are infiltrated with fat and for such cases this operation is not suitable. The most important and the largest number of cases of importance to

Fig. 6.—Condition present in perineum of an old man. The muscles are very thin and there is definite fat infiltration present.

be eliminated are those patients who are impotent from some psychic cause. Such patients should be treated by a neurologist.

Frequently men who are advancing in years begin to lose their sexual power, and such cases should be considered carefully before the operation is attempted. It is most important for the surgeon to determine the blood pressure of such men, as it is entirely possible for cerebral hemorrhage to accompany the violent exercise involved in sexual expression, if the patient's blood pressure is elevated or his blood vessels are diseased.

It has been found that the muscles of men over 60 years of age are rarely suitable for the performance of this operation because of the fact that they are often infiltrated with fat and do not have the proper resilience.

It is particularly important not to attempt this operation on any person who has a disturbance of the nervous system such as is found in tabes dorsalis or in any form of syphilis. Men who are suffering from premature senility should be excluded from the benefits of this operation because of the possibility of their getting into social complications as a result of being able to express themselves sexually.

## Results of Operation in Thirty-Three Cases

Case	Patient	Age	Last Erection	Last Normal Inter-course	Cause	Condition of Muscles	Post-operative Complications	Post-operative Days	First Post-operative Erection	First Postoperative Intercourse	Subsequent Experiences
1	D. P.	40	18 months	2½ years	Perineal fistula; seminal vesiculotomy 2½ years	Good	None	13	3 days	13 days	Regular and good; 7 times first 3 days; 4 times weekly to date
2	J. R.	31	3 years	3 years	Blow in left groin and penis	Good	None	9	5 days	30 days	3-4 times weekly; wife has recently given birth to a healthy baby girl
3	A. O.	38	19 years	19 years	Early excesses	Good	None	9	3 days	20 days	2 times weekly
4	H. L.	33	6 months	1 year	Early excesses	Good	Slight drainage	13	3 days	17 days	Satisfactory intercourse to date
5	S. H.	53	10 years	10 years	Advancing years	Fatty infiltration	Pneumonia; phlebitis; drainage	108	6 days	None, unmarried	Occasional erections
6	J. K.	39	5 months	6 months	Strain of muscles	Fair	None	6	2 days	24 days	Regular and satisfactory to date
7	P. K.	57	3 years	9 years	Perineal abscess nine years before	Moderate fatty infiltration	None	9	7 days	16 days	Fair
8	C. M.	42	5 years	5 years	Early excesses	Fair	None	7	3 days	21 days	Erections good; loses interest because of wife's delay
9	A. W.	42	3 years	3 years	Advancing years	Fair	Slight drainage	8	7 days	11 days	Many erections; premature; satisfactory of late; married recently
10	W. H.	63	20 years	20 years	Syphilis	Poor	Drainage	19	None	Unable to follow up	
11	H. H.	29	6 years	6 years	Weak musculature	Good	None	11	4 days	Unable to follow up	Satisfactory erections; single
12	J. D.	66	12 years	12 years	Old age	Fair	None	13	None	Unable to follow up	
13	L. S.	22	Present (semi)	2 years	Masturbation and sexual excess	Good	Inability to void; drainage	7	2 days	12 days	Many erections; entirely satisfactory intercourse; frequently
14	W. B.	65	4 years	4 years	Old age	Good for age	None	19	None	None	Not able to hold intercourse
15	M. M.	65	2 years	7 years	Prostatectomy 2 years; syphilis	Fair	None	9	None	None	
16	S. H.	28	Present (semi)	Never normal	Improper musculature	Good	Epididymitis; unable to void	21	7 days	.....	Occasional intercourse
17	S. H.	50	Present (semi)	Never normal	Advancing years	Fair	None	8	21 days	Right after plication	Satisfactory intercourse; recently married
18	J. C.	35	Present (semi)	4 years	Fall astride a pleket fence at 6 years of age	Good	None	10	8 days	Right after plication	Plication of suspensory ligament done 5/1/36; regular intercourse
19	P. B.	34	Present (semi)	5 years	Early excesses	Good	Slight drainage	11	4 days	12 days	Good
20	J. B.	25	Present (semi)	5 years	Fracture of pelvis and rupture of bladder 5 years ago	Good	None	7	2 days	10 days	Many erections; entirely satisfactory intercourse frequently
21	I. R.	50	Present (semi)	20 years	Advancing age	Fair	Drainage; could not void	19	20 days	22 days	Good
22	D. O.	50	1 year	1 year	Advancing age	Poor	Could not void	16	8 days	Satisfactory erections	Plication of suspensory ligament 4/20/36
23	H. F.	25	Never complete	Never	Pollomyelitis at age of 15	Good	Could not void	10	9 days	None; engaged to be married	Frequent erections
24	P. B.	44	3 years	6 years	Early excesses	Good	Could not void	12	4 days	No intercourse	Good erections; plication of suspensory ligament done
25	S. M.	53	6 months	6 months	Advancing years	Good	None	14	10 days	Many erections	Plication of suspensory ligament done
26	M. C.	33	Present (semi)	2 years	Early excesses	Good	Could not void	11	6 days	No intercourse	Good erections; plication of suspensory ligament done
27	P. N.	47	1 year	2 years	Advancing years	Good	Could not void	22	2 days	40 days	Strong erections; normal intercourse
28	K. M.	38	Present (semi)	10 years	Poor musculature	Muscles infiltrated with fat	Could not void	15	12 days	Some erections	Plication of suspensory ligament done; good erections
29	N. S.	54	Present (semi)	12 years	Advancing age	Fair	Could not void	15	4 days	Many erections	Plication of suspensory ligament done; good erections
30	W. S.	51	1 year	5 years	Advancing age	Good	None	8	2 days	Frequent strong erections	Plication of suspensory ligament done; result perfect
31	A. L.	45	Present	16 years	Poor musculature	Poor	Could not void	14	None in hospital	34 days	Plication of suspensory ligament done; 5 times in 2 weeks
32	C. C.	48	10 years	10 years	Advancing age	Very good	Could not void	11	None in hospital	Occasional erections	Plication of suspensory ligament done
33	R. C.	46	1½ years	1½ years	Poor musculature	Ischioavernosus good, bulbocavernosus poor	Could not void	9	None in hospital	Some erections	Plication of suspensory ligament done

NOTE.—Since this report was submitted, operations have been performed in eighteen additional cases. Some of these are too recent to report but for the most part the operations have been entirely satisfactory. The results are included in the summary but not in this table.

## SUMMARY AND CONCLUSIONS

1. Animal experiments indicate that ribbon gut is the best material for use in shortening the ischiocavernosus and bulbocavernosus muscles, as they do not cut through or cause necrosis, while the ordinary catgut does so.

2. Up to the time of publication, fifty-one men have been operated on by the method described in this communication; namely, by shortening the ischiocavernosus muscle on each side and plicating the bulbocavernosus muscle.

3. In order to accomplish the desired result, the operation must be skilfully performed, with just the right amount of shortening of the muscles. If the muscles are too tight, a constant painful erection will result; if not tight enough, satisfactory erections will not be produced.

4. The tightening of the two leaves of the suspensory ligament causes compression of the dorsal veins of the organ, thus aiding stasis and preventing collateral circulation developing to such an extent that it detracts from the success of the operation.

5. The success of the operation apparently depends on the use of ribbon gut, which does not tear through the delicate muscles as does ordinary twisted catgut.

6. Thirty-one of the fifty-one patients have been successfully relieved of their impotence. Of the eight unsuccessful cases, four were men over 63 years of age. Patient 10, aged 63, had had syphilis for twenty years, and a favorable result was neither expected nor obtained. Patient 12, aged 66, had been impotent for twelve years and was unimproved by the operation. Patient 8, C. M., was perfectly cured by the operation and was efficient for a period of about six weeks. Then he began to slump and has remained only partially efficient since. It is probable that the plication of the bulbocavernosus was not satisfactory, and we are planning to reoperate on this patient in an attempt to relieve the situation. Patient 14, aged 65, had been impotent for four years. No improvement resulted from the operation, although it was expected. Patient 15, aged 65, had a prostatectomy two years before and his last intercourse five years previous to that. He was unimproved by the operation. Three other cases failed for no apparent reason and eight are too recent to report.

7. It will therefore be seen that the aged men who have not profited by the operation have been those over 63 years of age; these have not been helped in any instance thus far. This may be a blessing in disguise, as the possibility of cerebral hemorrhage is not inconsiderable if men of this age are subjected to the increase in blood pressure coincident with the excessive exercise connected with sexual intercourse.

8. The most spectacular cures have been achieved in those rendered impotent by traumatic injuries to the perineum due to operation, rupture of the urethra by straddle injuries or other violence.

9. It is well to emphasize those cases in which this operation should not be attempted. These include patients with psychic impotence, persons who have had the nervous chain broken such as in cases of old syphilis, and patients of advanced age with high blood pressure.

10. There is nothing thus far to indicate that the relief will be other than permanent, although sufficient time has not elapsed for absolute certainty on this point.

TUBERCULOSIS OF THE SPINE AND  
SCOLIOSISAN IMPROVED TECHNIC FOR ARTHRODESIS OF  
THE VERTEBRAL JOINTS

CHARLES S. YOUNG, M.D.

LOS ANGELES

There are several well known operative procedures that have been used for the purpose of creating ankylosis of the vertebral joints, but none have been entirely satisfactory. Such operations should result in the production of a solid bony mass about and enmeshing the posterior part of the neural arches and spinous processes of several adjoining vertebrae.

It is a well established fact that an arthrodesis results in healing and fusion of the vertebral bodies in most cases of spinal tuberculosis. Arthrodesis has also been performed for many years in scoliosis to stabilize a section of the spinal column after the greatest possible correction of severe lateral curvature. The problem has been to devise an operation that would have the following qualifications: first, application to all regions of the vertebral column; second, reasonable certainty of arthrodesis without the development of pseudarthroses; third, minimum surgical shock, especially when the patients are young children.

The most widely known operative technics used to produce ankylosis of the spine are those described by Hibbs and Albee.

The Hibbs<sup>1</sup> operation is known as an intra-articular arthrodesis because the lateral articulations are invaded. In this procedure the spinous processes, the laminae and the articular processes are exposed subperiosteally. The cartilage is removed from the lateral articulations with a curet. Small sections of bone are raised from each lamina with a gouge and mallet and used to span the space between the laminae. The spinous processes are cut and fractured with specially designed cutting forceps so that they will lie in contact each with the one inferior. The periosteum and muscles are sutured in place to cover the exposed bone. This operation has many advantages. However, it has three disadvantages which one must consider: First, the use of the gouge and mallet to raise bone from the laminae causes trauma to the spinal cord and central nervous system through the impulse transmitted hydrostatically by the spinal fluid. This is manifested by a sudden increase in the pulse rate, which continues during the remaining time of the operation. Second, in the operation for scoliosis with severe rotation it is not techni-

Fig. 1.—Osteoperiosteal transplants on bases of spinous processes and laminae, the periosteal surfaces of the grafts being directed posterolaterally.

1. Hibbs, R. A.: An Operation for Pott's Disease of the Spine, J. A. M. A. 59: 433-436 (Aug. 10) 1912.

cally possible to remove the cartilage from the articular processes on the deep side. Therefore the operation cannot be performed completely as designed. In these cases fusion may not be complete and relapse in the deformity can result. Third, vertebral bone does not proliferate to the same extent as the bone tissue of the long bones. It is possible for a pseudarthrosis to develop in the region of operation for this reason,

Fig. 2 (case 1).—Preoperative lateral view, which reveals destructive disease in second and third lumbar vertebrae.

although the lack of continuity of bone chips is another cause of pseudarthrosis. The Albee<sup>2</sup> operation is known as the extra-articular arthrodesis because the lateral articulations are not invaded. In this procedure a tibial graft is inlaid in the spinous processes to bridge the vertebrae. This operation is not so practical for children because of the relatively small bone structure in the spinous processes. In adolescents and adults the Albee operation is used to its best advantage in lumbar tuberculosis with small or no kyphosis. Lumbosacral, thoracic and cervical disease makes the full thickness tibial graft present serious technical and mechanical difficulties when one attempts to implant it in the spinous processes for the following reasons: First, the sacral spinous processes are too rudimentary to be bisected and form a broad raw bone surface for fusion with a graft. Second, the thoracic spinous processes when bisected present very narrow and thin surfaces for the reception of transplanted bone. Third, the cervical spinous processes are so small after bisection that the insertion of a tibial graft in them is not practicable. In the consideration of the Albee operation one must take into account the fact that the impulse of the broad chisel used to divide the spinous processes causes hydrostatic trauma to the central nervous system through the spinal fluid. The hammering of the full thickness tibial graft into the angle formed by bisection of the spinous processes, as practiced by some surgeons, produces more hydrostatic impulses in the spinal fluid, which are manifested by a rapid increase in the pulse rate, the latter being of considerable concern to the anesthetist.

During the past seven years I have been performing an arthrodesing spinal operation which seems to have measured up to the requirements that have been presented.

#### TECHNIC FOR TUBERCULOUS DISEASE

In tuberculous disease of the vertebrae, the operation is indicated when the diagnosis is made if the condition

of the patient is sufficiently good to withstand any major surgical procedure.

The patient lies in the semiprone position with a sand bag under one shoulder and under the corresponding side of the pelvis and hip. The incision when no kyphosis is present may be longitudinal over the tips of the spinous processes. When there is a kyphosis the incision should be crescentic, beginning at the midline superiorly and curving laterally to return to the midline inferiorly. Towels are applied to the skin edges with large skin clips. The skin and superficial fascia are reflected until the supraspinous ligaments are exposed. The latter are divided in their midline longitudinally to expose the tips of the spinous processes, which are denuded. The interspinous ligaments are also divided longitudinally and are reflected laterally with the muscles, which are separated subperiosteally from the spinous processes and laminae. If the line of cleavage is kept within the ligaments and between the periosteum and bone, there is little hemorrhage. This subperiosteal dissection is continued laterally to the capsules of the lateral articulations. The separation of all soft tissue from the spinous processes and the posterior surface of the laminae is imperative. It is difficult in the exposure to divide the interspinous ligaments and reflect them completely, but every particle of these ligaments remaining on the spinous processes should be excised or curetted away. The operation should extend at least two vertebrae above and two below the diseased area.

In the thoracic region, if there is a prominent kyphosis, the tips of the spinous processes making up the angulation should be excised to decrease the visible deformity.

For the excision of osteoperiosteal grafts, a straight longitudinal incision is made over the middle of the

Fig. 3 (case 1).—Ten months after operation: healing and fusion of second and third lumbar vertebrae.

medial surface of the tibia after the application of a tourniquet. A curved incision may result in the division of the large saphenous vein unnecessarily. The superficial fascia is reflected, the shaft of the bone is exposed and the periosteum is incised by two parallel incisions outlining the medial surface of the bone for

2. Albee, F. H.: Transplantation of a Portion of the Tibia into the Spine for Pott's Disease, *J. A. M. A.* 57: 885-886 (Sept. 9) 1911.

the required length of the graft, which should be sufficiently long to extend the length of the exposed area on the vertebral column. The periosteum is divided further by another parallel incision midway between the other periosteal incisions. The outlined periosteum with a layer of cortical bone about 2 mm. in thickness is raised with a thin chisel or osteotome so that it can be removed in two linear sections, each

Fig. 4 (case 2).—Fifteen months after operation, showing healing and fusion of diseased vertebral bodies. Attention is called to proliferation of bone in region of spinous processes.

being half the width of the medial surface of the shaft at its narrowest part. The grafts should be bent between the folds of a towel moistened with physiologic solution of sodium chloride so that their cortical or raw surface will conform to the contour of the exposed vertebrae. After bending, each graft should be fitted (one on the right and the other on the left) so that its raw surface is in perfect contact with each lamina and base of spinous process (fig. 1). The periosteal surface of the grafts should be superficial.

The spinal periosteum, interspinous ligaments and muscles are sutured over these grafts to maintain them in position, deep interrupted sutures across each space between the spinous processes being used. For this purpose No. 3 chromic catgut is used in adolescents and adults, while No. 2 chromic catgut is used in children. A running suture of No. 1 chromic catgut in adults and No. 0 chromic catgut in children is used to unite the supraspinous ligaments and deep fascia.

In the lumbar and cervical regions, when there is a thick layer of subcutaneous fat, it is necessary to suture it with plain catgut. Closing of the skin and superficial fascia is made with vertical mattress sutures and running sutures of nonabsorbable material. Time can be saved in this operation by having the osteoperiosteal grafts excised from the tibia by an assistant, while the knee is held flexed 90 degrees.

Postoperative immobilization of the vertebrae is maintained by means of plaster-of-paris shells or body jackets. In cases of young children, plaster shells made and dried before the operation are used. The patient is strapped into either the anterior or the posterior shell to allow a change in position. For older children, adolescents and adults, Bradford frames are used until the stitches are removed. Then a plaster jacket is

applied with the patient on a canvas sling in the prone position. In lumbar disease the jacket should be extended to include the thighs. When there is a severe kyphosis a Bradford frame is unsuitable, so that immediately postoperative a firm bed with hard pillows is used until the stitches are removed, when a well padded plaster jacket can be applied.

Recumbency should be maintained for a period of from three to six months, the time being determined by the degree of healing revealed by roentgenograms. A back brace is applied following the plaster jacket and is worn for from six to nine months, this time also being determined by the healing shown in roentgenograms. During the entire period of convalescence the patients are required to include in their diet or take medicinally a sufficient quantity of calcium, phosphorus and vitamin D in order that there may be no deficiency of bone-forming essentials.

#### SCOLIOSIS

I have performed this vertebral arthrodesis on a few scoliosis patients. The proliferation of bone that followed the operation, and the stability of the fused section of the spinal column, were very gratifying. The operative technic was the same as for tuberculosis of the vertebrae. However, in two cases of extreme rotation of the vertebrae in the lumbar region it was possible to use only one wide graft. The latter was placed on the laminae and bases of the spinous processes of the superficial side. In these severe rotation cases a partial exposure of the spinous processes on the deep side was necessary in order to facilitate the longitudinal division of the interspinous ligaments.

Fig. 5 (case 3).—Right thoracolumbar structural scoliosis.

Postoperative immobilization of the scoliosis patients was maintained by head and pelvic traction and by plaster turnbuckle jackets for periods varying from four to six months. Supporting apparatus consisting of back braces and corset braces was used for the following six to eight months.

## COMMENT

The extensive proliferation of bone, to produce ankylosis of a section of the vertebral column following osteoperiosteal transplantation as described, is dependent on Wolff's law. The latter is illustrated particularly in one case of scoliosis with extreme rotation, in which newly formed bone stands out in relief in the roentgenogram. The shadow appears in total density to be greater than all the other contiguous bone structures in the vertebral column (fig. 7).

It is reasonable to believe that this arthrodesis is dependent largely on a very thorough subligamentous and subperiosteal exposure of the posterior part of the neural arches and careful fitting of the osteoperiosteal grafts, so that the raw surfaces of the latter are in broad contact with the raw surfaces of the laminae and bases of the spinous processes. A combination of this operation with bone chips from the laminae and imbrication

Fig. 6 (case 3).—Five and one-half months after operation.

cation of the spinous processes will lead to fusion in most cases, but it makes the operation unnecessarily complex and the rationale is changed.

With regard to instruments used, I found that the conventional periosteal elevators in general use were unsatisfactory for subligamentous and subperiosteal exposure of the vertebrae. The handles were concave or too small, so that the hand and forearm muscles of the surgeon became cramped in the tedious dissection. An elevator with a large convex handle and a sharp elevator edge for adults and a dull rounded edge for children was designed to obviate this difficulty.

## STATISTICS

Feb. 1, 1936, there were seven cases of tuberculosis of the vertebrae in which more than one year had elapsed since operation. Of this group the first operation was performed Sept. 16, 1930, and the last Jan. 3, 1935, so that sufficient time has elapsed to make a fair estimation of results. The youngest patient was 2 years and the oldest 47 years of age. Originally it was considered that the osteoperiosteal grafts would be pliable for accurate fitting in children and adolescents only.

However, in the two adults, thin grafts were removed from the tibia with little splintering, so that they could be bent to approximate the curve required. All the tuberculosis patients had an uneventful convalescence. Healing has resulted in the effected vertebral bodies, and ankylosis has occurred in the section of the vertebral column on which the operation was performed. One patient, a girl of 5 years, with extensive destruction of the bodies of five thoracic vertebrae, a tuberculous abscess and a severe kyphosis, has an arthrodesis extending from the fifth thoracic to the first lumbar vertebrae. Subsequent to the operation, Aug. 22, 1931, there was progressive fusion of the remaining portions of the diseased vertebral bodies and a proliferation of bone from the transplants as revealed by roentgenograms. The patient became clinically well excepting for the deformity and hyperactive knee jerks, which were present prior to the arthrodesis. As there were no symptoms the mother of the child did not consider it necessary to bring the latter in for observation for a period of more than fifteen months. The parents noticed that there was a rapid increase in the deformity a few weeks prior to readmittance. Roentgenograms revealed a new destructive lesion in the fourth thoracic vertebra, which was superior to the preceding disease in the lower thoracic vertebrae. A second operation was performed May 22, 1936. The site of the first operation was exposed in its superior part and a large mass of dense bone was found to enmesh and fuse with the spinous processes and laminae. The operation was extended superiorly to include three more vertebrae. Osteoperiosteal transplants were placed on the bases of the spinous processes and laminae. Inferiorly the grafts were inserted under the reflected periosteum of the bone mass which resulted from the first operation.

Feb. 1, 1936, there were six cases of scoliosis in which operation had been performed more than three years before. These patients were adolescents. There was one case of rachitic scoliosis, two of developmental structural scoliosis, and three cases caused by anterior poliomyelitis. This group of patients had no postoperative complications, and fusion resulted so that there is good stability of the vertebral column in each case.

## REPORT OF CASES

Only four case reports are given, because this number will serve to illustrate the types of patients on whom the operation has been performed.

CASE 1 (figs. 2 and 3).—A. T., a Japanese boy, aged 6 years, admitted Dec. 27, 1927, had a kyphosis with the apex of the angulation at the spinous process of the second lumbar vertebra. The thorax leaned toward the left, so that the patient had difficulty in maintaining his equilibrium when walking. The sacrospinalis muscles in the thoracic and lumbar regions were in a state of spasm. There was a limitation of movement in the dorsolumbar region of the vertebral column. The Pirquet reaction was positive.

Roentgenograms showed a destructive process in the bodies of the second and third lumbar vertebrae and a narrowing of the intervertebral space. In the anteroposterior view the second lumbar vertebra was tilted downward on the left and the destructive process appeared more advanced in it and the cartilage inferior to it.

The diagnosis was tuberculosis of second and third lumbar vertebrae.

Recumbency on plaster shells was instituted primarily, because the mother of the patient refused consent for an arthrodesis. Fusion of the vertebral bodies did not occur after nearly three years, although the disease did not make any definite progress during this time.

Sept. 16, 1930, an arthrodesis was performed by implantation of a tibial osteoperiosteal graft on each side of the bases of the

spinous processes and laminae from the twelfth thoracic to the fifth lumbar vertebrae. Sept. 24, 1931, one year later, the patient from a clinical standpoint had made a complete recovery with the exception of the loss of spinal movement between the fused vertebrae. The kyphosis deformity had not increased and the lateral deviation of the thorax had been overcome. The boy went to Japan in 1932 to receive his education there. In a communication from the family physician May 12, 1936, the latter reported that there has been no relapse and that the patient is clinically well.

CASE 2 (fig. 4).—G. C., a man, aged 41, admitted Dec. 19, 1934, had a kyphosis with the apex of the angulation at the spinous process of the eleventh thoracic vertebra. The sacrospinalis muscles in the thoracic and lumbar regions were in a state of spasm. Movement in the dorsolumbar region of the vertebral column was very restricted in its range. Roentgenograms showed a destructive process with wedging of the eleventh thoracic vertebral body with an almost complete loss of the intervertebral spaces between the tenth and eleventh and the eleventh and twelfth thoracic vertebrae. There was an

esses and laminae from the ninth thoracic to the third sacral segment. Sept. 16, 1933, the turnbuckle jacket was removed, ten months after the operation. The scoliosis was not apparent on physical examination, although the angulation of the ribs on the right side detracted from the appearance of the back and the improved alinement of the vertebrae.

CASE 4 (fig. 7).—A. G., a school boy, aged 14 years, admitted July 19, 1929, had a flaccid paralysis, partial or total, of the muscles of the back, the abdomen and the lower extremities. The back showed a severe left thoracic and a right thoracolumbar scoliosis. The scoliosis was so extreme that the costal margin impinged on the pelvis in the standing or sitting position. The thorax was badly deformed, with extreme angulation of the ribs on the left side. There was severe paralytic involvement of both lower extremities, the right being practically a dangle leg. Other surgeons had previously performed stabilizing operations on both feet and a fusion operation on the thoracic spine.

The diagnosis was anterior poliomyelitis; left thoracic, right thoracolumbar scoliosis.

July 24, 1929, an arthrodesis was performed by implantation of an osteoperiosteal tibial graft on the superficial side of the laminae and spinous processes from the twelfth thoracic to the fifth lumbar vertebrae inclusive. The operation was not preceded by corrective measures to diminish the thoracolumbar curve on account of the previously fused thoracic vertebrae, the extreme deformity of the thorax and the severe rotation of the lumbar vertebrae. It was believed that the separation of the spinal ligaments and postoperative head and pelvis traction, which was applied, would lead to all the practical correction of the scoliosis that was possible. The brace was removed April 22, 1930, approximately nine months after the operation. The stability of the spine was such that there was no pain or sense of weakness in the back. When the last inspection of this patient was made on March 19, 1936, he was employed. In the follow-up roentgenogram of Dec. 26, 1935 (fig. 7) the thoracic scoliosis at the site of the first arthrodesis showed a relapse, while in the thoracolumbar region there was revealed a dense mass of bone which obviously prevented any increase in the deformity.

#### CONCLUSIONS

1. An arthrodesis of adjoining vertebrae can be performed by transplantation of long flexible osteoperiosteal grafts from the tibia to the laminae and bases of the spinous processes.
2. This operation has resulted in healing and fusion of vertebrae in which there was a tuberculous osteitis (Pott's disease).
3. After the greatest possible correction of the deformity in scoliosis, a section of the vertebral column can be stabilized by this operation to prevent relapse and to make the use of braces and supporting apparatus unnecessary.

**Artificial Insemination.**—There has been, from time to time, a good deal of unfortunate newspaper discussion on the subject of artificial insemination and "test-tube babies." Many women have gotten the impression that the method is of frequent value in the treatment of sterility. This is not the case. In normal intercourse the sperm is deposited in the immediate vicinity of the mouth of the womb, and the spermatozoa quickly enter the uterus. At times, however, the secretions or discharges of the canal may make this difficult, so that it is conceivable that in the rare case the injection of the sperm into the uterine cavity with a syringe would give a better chance of pregnancy. In cases of male sterility—and these furnish the chief excuse for artificial insemination—there is no doubt that the method is of at least some value, for without it the chances of the woman are nil unless she sacrifices her marriage vows. If a woman thinks, however, that a single test-tube insemination is sure to result in conception, she will practically always be sadly fooled.—Novak, Emil: *The Woman Asks the Doctor*, Baltimore, Williams and Wilkins Company, 1935.

invasion of the destructive process into the bodies of the tenth and twelfth thoracic bodies. A shadow indicating considerable perivertebral thickening was present in the anteroposterior view.

The diagnosis was tuberculosis of the tenth, eleventh and twelfth thoracic vertebrae.

Jan. 3, 1935, an arthrodesis was done by implantation of an osteoperiosteal graft on the bases of the spinous processes and laminae from the seventh thoracic to the third lumbar vertebrae. Jan. 3, 1936, the section of the vertebral column at the site of the operation was ankylosed. There was no spasm of the sacrospinalis muscles. The patient was clinically well and had returned to his occupation.

CASE 3 (figs. 5 and 6).—D. S., aged 14 years, admitted July 26, 1932, had a right structural dorsolumbar scoliosis with extensive rotation. There was an angulation of the ribs posterior on the right side. The right scapula was elevated and abducted. Limitation of right lateral bending of the trunk was present. An anteroposterior roentgenogram showed a right thoracolumbar scoliosis.

The diagnosis was right thoracolumbar scoliosis.

July 26, 1932, an arthrodesis was done by implantation of tibial osteoperiosteal grafts on the bases of the spinous proc-

## GENERAL ACQUIRED ANHIDROSIS

REPORT OF A CASE AND INVESTIGATIONS OF THE  
HEAT REGULATION AND CIRCULATION

MOGENS FOG, M.D.

COPENHAGEN

A total disappearance of the ability to perspire is rarely seen. The sporadic and familial cases of general anhidrosis that have been reported in the past (Quilford,<sup>1</sup> Loewy and Wechselmann, Richardson,<sup>2</sup> Tannhauser<sup>3</sup> and others) resulted from a congenital and general developmental anomaly of the dermic organ; i. e., an ectodermal dysplasia.

Nowhere in the medical literature, however, have I been able to find a description of a case such as the one cited here; i. e., in which cessation of the function of sweating occurred in a person who had previously been perfectly normal in this respect. A case of this sort gives rise not only to diagnostic observations and examinations but also to a number of pathophysiologic ones, which, among other things, serve to throw light on the normal function of perspiration.

Fig. 1.—Biopsy. Skin from the axillary region. Apocrine glands with low cubical epithelial cells. Stained by hematoxylin-eosin.

## REPORT OF CASE

**History.**—A man, aged 25, a patient in the Rigs Hospital, department B, from July 26 to Nov. 9, 1933, was the fifth of six siblings. The family was well, with no history of sweat disturbances, ectodermal dysplasia or metabolic or nervous diseases.

The patient had had pneumonia in infancy and later the common diseases of childhood. At 17 he was treated for coxa vara traumatica sinistra with osteotomia subtrochanterica. There have been no symptoms from the extremities since.

At 21, in 1927, the patient contracted an acute febrile illness thought to be common influenza with blepharitis. After spending twelve days in the hospital he resumed work, although he did not feel well. Several times during the next two months his temperature rose, reaching 39 C. (102 F.) in the evening. At the beginning of April he was compelled to go to bed with a temperature of 41 C. (105.8 F.). He was extremely ill and during the course of the next few days he developed edema of the pharynx, face and hands, and a red spotted exanthem appeared over the entire body. The latter soon disappeared. For a fortnight he had a high fever and was drowsy, although he did not display typical somnolence, diplopia, cervical rigidity

or severe headache. Figure 4 shows the temperature curve of this period and the subsequent months. Following a severe nasal hemorrhage the patient improved, but nevertheless he remained in bed for many weeks. There were occasional recurrences of slight temperature elevation. There were no abscesses or exanthema but the patient's skin peeled off and all his hair fell out.

In June he again had fever accompanied by diarrhea. Widal's reaction on the serum, which had previously been negative, was now positive, thus determining the presence of paratyphoid fever. The urine and feces, however, reacted negatively.

Fig. 2.—Preparation as in figure 3. Cystic degeneration of apocrine glands. Below, normal eccrine glands.

During the course of the summer the patient's general condition improved and in August he returned to his post as clerk in a grocery shop.

In September he attended a football match in the blazing sun and suddenly become indisposed. He had a sensation of pressure above the precordia, and his face, which was greatly congested, felt burning hot. For the first time he noticed that he was not perspiring anywhere on his body.

Fig. 3.—Preparation as in figure 3. General view showing apocrine glands in varying degrees of degeneration. Normal eccrine glands.

Since then the patient has never sweated. He maintains that previously, when it was warm or when he was working, he perspired quite normally, at times even excessively. This also applies to his long febrile illness.

His condition since September 1927 proved to be very troublesome and he not only had to alter his way of living considerably but also felt himself in danger of giving up his work.

His chief complaint was of attacks similar to that suffered when he first discovered the nature of his illness. When he walks rapidly, especially in the sun, or engages in manual labor, he becomes indisposed. Particularly his face, but also the rest of his body, feels overheated; he has dull pain in the

Read before the Danish Neurologic Association in September 1933.

Translated from the Danish by Elsie-Marie Werner Kørnerup, A.B. From the Rigs Hospital, Department B (physician in chief, Prof. Erik Warburg, M.D.).

1. Quilford, S. H.: Wien. med. Wchnschr. 33: 1116, 1883.

2. Richardson, H. B.: J. Biol. Chem. 37: 397 (Feb.) 1926.

3. Tannhauser, S. J.: Hereditary Ectodermal Dysplasia of the "Anhydrotic Type," J. A. M. A. 106: 908 (March 14) 1936.

precordia, palpitation, dyspnea and often painful paresthesias in the face and the peripheral parts of the extremities. Frequently the attacks do not come on until he has stopped working or has come to a cool place. The symptoms, including the dyspnea, may then last for as long as an hour. He is quite exhausted after these attacks and is unable to resume work. During a short febrile illness in 1932 he felt much worse when his temperature was between 38 and 39 C. (100.4 and 102 F.) than previously when he had suffered identical temperature elevations. He noticed that the discomforts which he experienced usually made themselves manifest just after meals and during periods when he ate heavy and extremely "nourishing" food.

Besides the permanent absence of sweat secretion, the patient complains that his skin has become dry and scaly. This is especially true of his face, and he has to use cold cream two or three times a day.

He has always been inclined to become fat, but during his illness in 1927 he lost considerable weight. Since then, however, he has again gained 11 Kg. (24½ pounds).

The hair on his head, which fell out during the febrile period, has largely grown in again.

Except for some months in 1929, when he suffered from insomnia that did not respond to ordinary hypnotics, he has always been normal with regard to sleep.

Evacuation, urination and digestion show no abnormalities. Likewise his lacrimal and salivary secretion is normal. During the attacks, however, there is often a profuse thin secretion from the nose. Sexual desire and sexual life, as well as his mental state, are said to be normal.

As previously mentioned, since the onset of the anhidrosis the patient has had to make a number of adjustments in his way of living. He usually keeps quiet, walking slowly and preferably not at all on warm days, when a quarter of an hour's walk is enough to call forth the discomforts described. He does not do much bicycling; he no longer dances, and he is unable to do his full share of work. In the beginning of the summer of 1933 he felt quite incapable of working and was therefore admitted to the hospital.

**Clinical Examination.**—Psychiatric: Mentally the patient is intelligent. He possesses excellent understanding of his condition and has the ability to observe it. He has emotional stability.

**Somatic:** The patient is well proportioned with no symptoms of endocrinologic abnormalities. His weight is above average, 74.4 Kg. (163.6 pounds) and his height 164 cm. (5 feet 5 inches). The layer of subcutaneous fat tissue is particularly thick on the thorax and mammae; the extremities are normal, yet the wrists, hands and feet are exceptionally small, in fact, almost feminine (fig. 5).

The thyroid gland is normal. The rectal temperature is normal.

The hair on the head is thin as in seborrhea; the axillary and pubic hair is normal. Especially on the face and extremities the skin is very dry and scaly but without myxedematous changes.

Encircling the abdomen and lumbar region is seen a segmental, clearly defined stripe of brown pigmentation. This is presumably congenital. (A sister is said to have the same anomaly.)

Clinical, roentgenologic and electrocardiographic examinations of the heart showed nothing abnormal. The lungs are likewise normal.

X-ray examination of the pituitary region is negative.

**Neurologic Examination.**—Pupillary reaction, optic movements and other functions of the cranial nerves are normal. Tone, strength, coordination, superficial and deep sensibility, as well as reflexes, are normal in the extremities; the Babinski phenomenon is absent; the gait is free; there is no tremor, oligomimicry or bradykinesia.

The naso-ocular reflex (Wernöe), pilomotor reflex and spontaneous vasomotor reactions (flushing and blanching) are normal; there is lively dermatographism with urticarial reaction.

**Laboratory Examinations.**—There were no pathologic elements in the urine; diuresis was increased, averaging 2,000 cc. (measured for forty-two days, minimum 1,400 cc., maximum 2,600 cc.); the concentration was correspondingly low. Hemo-

globin was 88 per cent, the sedimentation rate 5 mm. an hour. The Wassermann reaction was negative; blood pressure 130 systolic, 90 diastolic. The basal metabolism was from 98 to 92 per cent (Benedict). The spinal fluid was bloody, with a normal protein content and a negative Wassermann reaction. Ewald's test meal: quantity 113 cc., congo 42, phenolphthalein 50.

**Summary.**—A man, aged 27, had at the age of 21 a long febrile disease (paratyphoid fever). Since then he has not been able to perspire and under circumstances in which sweat secretion usually appears (heat, fever, work) he gets attacks of indisposition, precordial pain, palpitation, dyspnea and congestion. There is no objective sign of organic nervous disorder or metabolic disease. The patient's skin is dry and scaly but otherwise shows nothing abnormal. The heart is seen to be normal. Diuresis is increased.

It is not unusual to come across patients who maintain that they "cannot perspire." Closer investigation of these cases reveals, however, that the secretion is present although reduced.

Therefore the first task in a case such as I have described is to verify the patient's statement that he is incapable of perspiring under all circumstances. With this purpose in mind the following experiments were carried out:

**Artificially Produced Fever.**—A preparation of sulfur and olive oil was injected intramuscularly (first day, 0.5 cc.; second day, 1 cc.). The rectal temperature rose to a maximum of

Fig. 4.—Temperature curve during illness of patient in 1927 and subsequent months.

38.1 C.; i. e., the same reaction as is seen in healthy persons. The skin temperature graded on the feet went up from an average of 32.9 C. (91.2 F.) to 34.2 C. (93.5 F.).

There was great congestion and the patient did not feel well. No sweat secretion was seen.

**Exposure to High Exterior Temperature.**—The patient's body and extremities were placed in a heating chest in which the initial temperature was 35 C. (95 F.), rising in the course of ten minutes to 50 C. (122 F.). From the very start he felt distressed; he became more and more congested and at the end of nineteen minutes the experiment had to be interrupted, as he was exceedingly ill with dyspnea, small, weak and rapid pulse, and râles on the posterior surfaces of both lungs. His skin was scarlet but without a drop of perspiration. He recovered very slowly. By mistake the patient's temperature was not taken. Clinically the condition had to be designated "cardiac insufficiency."

**Administration of Pilocarpine.**—One milligram of pilocarpine hydrochloride was injected intravenously. This caused a slight congestion of the face and subjective sensation of warmth but no sweat secretion. Thereupon 5 mg. of pilocarpine was injected, producing more pronounced vasomotor reaction and profuse salivation, but not a trace of secretion from the skin.

These investigations permitted me to conclude that the patient was right in saying that his sweat secretion had disappeared. Moreover, the experiment in the heating chest had given a good idea of the serious symptoms that were capable of developing in this patient. He maintains that he has been just as ill as in the heating chest twice since the onset of his illness, but that since

then he has avoided subjecting himself to conditions that might possibly bring on such a severe attack.

In view of the length of time the patient's illness has lasted (six years) it was deemed desirable to find out to what degree the sweat glands in his skin were present or had undergone regressive changes. The decided symptoms from the skin which were present during the patient's acute illness (exanthem, peeling and loss of hair) suggested the possibility of a primary disorder of the dermic glands themselves. Because of this a biopsy of the axillary skin was undertaken.

**Histologic Examination** (Dr. Sven Christiansen).—The epidermis and papillae were normally developed. Numerous lumens of sweat glands were seen in the corium (figs. 1, 2 and 3). About one half of these had the structure characteristic of normal apocrine glands; i. e., the cavity was covered with epithelial cells varying from low cubical to cylindric ones. The

latter had tongue-shaped shoots of protoplasm projecting into the lumen, where, in addition, fragments of discarded protoplasm were to be found. The rest of the glands proved to be abnormal. They were nearly cystic hollows, covered with absolutely flat cells, only the nuclei of which were clearly visible. The iron test (Tirmann and Schmelzer's method) showed only a trace of iron in the first group of cells described and none in the second.

The eccrine glands revealed nothing abnormal.

Thus it is seen that the histologic picture shows reduced function of the still existing glands and advanced degeneration of the rest. It is interesting to note in this connection that pilocarpine did not succeed in provoking secretion of the glands, in spite of the fact that about one half

Fig. 5.—Appearance of patient at time of examination.

of these were found to be morphologically normal. This seems to confirm Müller's<sup>4</sup> statement that the effect of pilocarpine on perspiration disappears after the interruption of innervation.

At the same time the result of the histologic examination directs attention to a consideration of the localization of the disorder. As I mentioned at the beginning of this account, in the previously reported cases of general anhidrosis there were general developmental anomalies in the skin, one of which was a complete lack of normal sudoriferous glands.

In my patient it is found that the secretion of sweat ceased despite the fact that a large number of the glands are still present. It must be regarded as indisputable that the origin of his disease must be sought in the septic condition in which he found himself in 1927 and which doubtless affected the innervators of the sweat glands. The general nature of the disease indicates that the disorder is not to be sought in the peripheral

neuron, the sympathetic nerves or the ganglions in the sympathetic trunk. Furthermore, the elective lesion of the glandular nerves, without the vasomotor nerves of the skin also suffering and likewise the partial degeneration of the glands themselves, argues against such localization.

In the central nervous system sweat innervation is represented by centers in the lateral horn of the medulla spinalis, in the medulla oblongata and in the cerebrum. The elective but nevertheless general extent of the disease does not speak in favor of spinal localization. On the contrary, attention is focused on those centers of sweat secretion which have been shown to be related to the heat regulation center in the cinereum (Isenschmid,<sup>5</sup> Dieden,<sup>6</sup> and others). However, peculiar that a cerebral disorder should cause a total and permanent cessation of the function of perspiration. In transverse lesions of the spinal cord in both man<sup>7</sup> and animals<sup>8</sup> the secretion was seen to return in from twenty-five to seventy-five days after the trauma. Only one case has been reported<sup>9</sup> in which a lesion such as this produced permanent cessation of sweat in the regions affected.

I realized that my assumption that the patient's pathologic condition was localized to the hypothalamic center would be confirmed if it were possible to show symptoms of a related disorder of other functions attributed to the activity of the hypothalamic cerebral regions.

In spite of widespread experimental and clinical experience there are, as yet, very few morbid phenomena to which, in this respect, one can ascribe local diagnostic worth. It cannot be said that my patient displays any such pronounced symptoms. His moderate adiposity might be explained by the sedentary life that he has been compelled to lead for a number of years. His diuresis is increased—it is about 2,000 Gm. of urine daily and the specific gravity is correspondingly low. This may possibly be interpreted as an indication of a lesion of the tuber cinereum, since the disappearance of the sweat secretion cannot be assumed to influence the diuresis during confinement to bed, consumption of ordinary fare and existence under everyday living conditions.

The cutaneous insensible perspiration, which constitutes about 30 per cent of the total water excretion of the organism, must be interpreted simply as a physical process of evaporation which is independent of the function of the sweat glands and therefore in this case scarcely compromised. The increase in the diuresis is, however, too slight to permit one to consider the presence of a manifest diabetes insipidus. Furthermore, observation of the patient thus far has given me no reason to believe that there was anything wrong with the heat regulation. His body temperature was normal and showed the usual daily rhythmic fluctuations. Following injection of a preparation of sulfur and olive oil, his temperature rose just as much as a normal person's does after the same dose. Yet, notwithstanding this, a closer investigation of the patient's heat regulation was considered desirable—not for local diagnostic reasons but for pathophysiologic ones. A case such as the foregoing serves to throw light on the significance

of cutaneous secretion of water in maintaining normal bodily temperature during increased heat production in the organism.

Before I describe the other experiments to which the patient was subjected I shall call to mind the various factors pertaining to heat regulation.

Chemical heat regulation sets in particularly under circumstances in which the exterior temperature is

Fig. 6.—Experiment 1: Patient dressed, without ventilator.

reduced, i. e., when there is greater heat production in the body. This is accomplished by muscular contraction and more specific metabolic increase.

Physical heat regulation exercises its action through variations in the amount of heat given off by the body. This takes place in various ways: (a) through radiation from the surface of the skin, (b) through conduction and heat currents from the surface of the skin, (c) through evaporation from the lungs and skin, (d) through warming of ingested food and inspired air.

A nude person lying in a horizontal position gives off heat according to the following approximate figures: radiation, 70 per cent; conduction and currents, 5 per cent; evaporation through the lungs, 10 per cent; evaporation through the skin, 15 per cent. The other aforementioned factors (d) play an inconsiderable part.

Under normal conditions such as this perspiration does not, as I have said before, act as a link in heat regulation. On the other hand, it becomes a very considerable factor under two quite different conditions:

1. When the giving off of heat by means of radiation and conduction is hindered (in cases in which the exterior temperature approaches or exceeds the skin temperature).

2. During an increase of heat production in the organism; for example, during muscular activity when, at the same time, a peripheral dilatation of the dermic blood vessels causes constantly increasing radiation and conduction, and increased pulmonary ventilation results in greater excretion of water through the lungs.

In a definite experiment Rubner and Lewaschew<sup>10</sup> found that the amount of perspiration from a man placed in a room temperature of 28.9 C. (84 F.) corresponded to one half of the total loss of heat. During muscular activity the quantity of perspiration may reach 3 or 4 liters a day (approximately 3½ or 4½ quarts), corresponding to from 1,600 to 2,150 calories.

10. Rubner and Lewaschew, cited by Müller.<sup>4</sup>

In the experiment already described, namely, when the patient was placed in a heating chest, the temperature of which prevented heat being given off by means of conduction and radiation, dangerous symptoms of cardiac insufficiency appeared. Contrary to this, a normal person who is subjected to similar conditions can make up for the lack of radiation by increased evaporation. In the case reported here this compensation was impossible because of the anhidrosis and, consequently, an interruption in the heat regulation had to occur.

Despite this, however, there was no proof that the patient would be as badly off during muscular activity. The possibility existed that an increase in dissipation of heat by conduction and radiation would be able to compensate for the absence of regulation by evaporation.

In order to throw more light on this question a series of experiments<sup>11</sup> were undertaken by means of Krogh's cycle ergometer, which permits exact evaluation of muscular activity.

During the experiments the room temperature was between 19.4 C. and 20.1 C. (66.9 F. and 68 F.) and the patient did work of 360 Kg. per minute, corresponding to an ordinary bicycle ride up a very slight incline. During the first two experiments the patient was fully dressed; during the third he wore only a suit of thin cotton underwear. By way of comparison, an identical experiment was performed on a normal person of the same age, height and weight, and who, dressed just as the patient, did the same amount of work. Figures 6, 7, 8 and 9 illustrate the results.

In the first two experiments when the patient was dressed and the possibility of giving off heat through conduction and radiation therefore was relatively poor, it was seen that both his pulse rate and the rate of respiration increased much more than in the healthy person. At the same time, contrary to the latter, the

Fig. 7.—Experiment 2: Patient dressed, without ventilator.

patient suffered greatly from working. His skin was hot and red but dry. The other man's skin was moist both under his clothes and where it was exposed.

When similar work is done by normal individuals their blood pressure rises to 160 or 170 mm. of mercury systolic and, as experience has shown, it remains high during the entire period of work. In the second experiment, however, I saw that after the lapse of

11. The experiments were performed in the university zoophysiology laboratory. Professor Krogh lent me the apparatus and Dr. Phil. Marius Nielsen performed the experiments on pulmonary ventilation and basal metabolism.

fifteen minutes the patient's blood pressure fell and simultaneously he stated that he felt exceedingly ill. At the same time the pulse rate became even more rapid than before.

On the other hand, I noted that the patient's temperature rose only approximately 0.1 degree centigrade during the actual work (in experiment 1, from 37.68 to 37.79 C.; in experiment 2, from 37.60 to 37.71 C.), on

Fig. 8.—Normal person dressed, without ventilator, under the same conditions and doing the same amount of work as the patient in experiments 1 and 2.

the whole not more than in normal persons. This shows that contrary to Richardson's patient, who had a congenital lack of sudoriferous glands, this patient is able to regulate his temperature during increased heat production in the organism. This regulation, however, causes him severe discomfort; i. e., symptoms that remind one of cardiac insufficiency.

Furthermore, it was striking that the patient's condition was decidedly worse than that of a normal person's after the experiment. For as long as forty minutes after he had stopped working he was greatly congested, felt exhausted and had a pulse rate of 120 per minute. The normal person recovered much more quickly and his pulse became normal in the course of ten or fifteen minutes. These observations turned my thoughts to the possibility of his unpleasant sensations being due to latent heart disease and independent of the lack of perspiration. Yet as I mentioned previously, ordinary clinical, x-ray and electrocardiographic examinations showed no sign of cardiac disorder.

This, however, did not entirely exclude the possibility that the "reserve strength" of the heart was reduced and that even during moderate exertion this made itself evident by a threatened insufficiency. In order to investigate this possibility the patient had to be allowed to do the same amount of work under conditions that provided the best opportunity for the giving off of heat by means of heat currents, conduction and radiation.

Therefore the patient was subjected to the same sort of experiment as the foregoing one, but this time he had on only a suit of thin cotton underwear and a strong current of air from a fan was turned on him. As previously mentioned, normally the giving off of heat by means of conduction and currents is insignificant. These factors were, however, now given the opportunity of becoming important.

The result of the experiment (fig. 9) showed that the patient's heart was quite capable of meeting the

demands placed on it under these conditions. It is seen that the patient's pulse rate did not increase abnormally, and soon after he had stopped work it returned to the original figure. Moreover, his rate of respiration increased only moderately and his blood pressure remained high during the whole time he was exerting himself. In addition, he was able to keep at work for forty-five minutes, against a maximum of twenty-five previously and, what is more, he stated that he was without subjective discomfort; indeed he maintained that he had not felt so well for years, since in all that time he had not been able to take such violent exercise without resultant indisposition.

In spite of his anhidrosis, the patient is able to maintain normal heat regulation during exertion. Yet this is possible only through redirection of heat regulation to heat elimination by means of conduction and radiation. In order that this may keep pace with the heat production in the organism, so violent a peripheral vascular dilatation has to take place in the patient that the blood is diverted to the dermic vessels to such an extent as to entail circulatory insufficiency. This is seen to appear in the second experiment (fig. 7) in which there was a fall in blood pressure plus a corresponding additional increase in pulse rate.

The metabolism tests show that the patient's consumption of oxygen while working corresponds to that of the healthy man. Since his basal metabolism is within the boundaries of normality, one must assume that his efficiency is equal to that of the normal individual (about 20 per cent).

Determinations of pulmonary ventilation prove that when dressed the patient's air exchange is somewhat larger than is normal. When he is undressed, it is less than in the normal individual. The deviations are, however, rather inconsiderable and no doubt lie within the physiologic fluctuation limit for untrained persons.

By means of determinations of the basal metabolism and pulmonary ventilation, it is possible to get an idea

Fig. 9.—Experiment 3: Patient undressed (tricot) with a ventilator in the room.

of the heat production in the organism of the two persons experimented on, and since the bodily temperature is practically constant, one thereby gets a direct expression of the amount of heat given off.

If a mixture of fat, carbohydrates and protein undergoes combustion in the body, every liter of oxygen used is equal to 4.82 calories. According to this the patient's heat production was, in experiment 1, 5.8

calories per minute; in experiment 2, 5.7 and 5.8 calories per minute respectively, and in experiment 3, 5.4 and 5.25 calories per minute. The normal man's was 5.73 calories per minute in the same unit of size.

Approximately 27 Gm. of water-vapor per square meter is given off under the given degree of humidity in the room. It takes 580 gram calories of heat to evaporate 1 Gm. of water at 30 C. (86 F.); this applies both to pulmonary and to skin evaporation. On the basis of this, the loss of heat by evaporation from the lungs could be computed in all experiments. It proved to constitute the following percentage in the patient: experiment 1, 11 per cent; experiment 2, 11 and 10 per cent, respectively; experiment 3, 7.4 and 7.6 per cent. In the control subject it was 9 per cent of the total loss of heat.

In the patient, the remaining 5.15, 5.11, 5.26, 5.0 and 4.48 calories per minute had to be disposed of solely through currents of heat, conduction and radiation. The normal man, on the other hand, was able to give off the other 5.17 calories per minute both in this manner and by means of cutaneous evaporation.

Unfortunately we could not undertake any reliable weighing before and after the experiments. It is therefore impossible to give any definite figures as to how much of the cutaneous loss of heat was given off by the control subject in the form of perspiration. As mentioned, he perspired and his clothes were damp during the work. If, as seems reasonable in this moderately adipose person, from 2 to 3 Gm. of sweat was thus excreted per minute, it means (figured according to the heat used for evaporation) that about 30 per cent of the cutaneous loss of heat took place by means of evaporation. The patient, who is of about the same size and weight, had therefore to give off approximately  $33\frac{1}{2}$  per cent more heat per minute through conduction and radiation than would have been necessary if his sweat secretion had been normal.

As long as he works fully clad, he is forced to suffer such extreme dilatation of the cutaneous blood vessels, and thus such marked diversion of blood to the skin, that symptoms of circulatory insufficiency arise. When he is vigorously fanned and wears nothing but thin underclothing, conditions are so much improved that compensation does not endanger the circulation. The numerical values that we observed, however, permit only a rough estimate of conditions.

The peculiar thing about this case is, above all, the fact that the heat regulation is maintained at the expense of the circulation. Doubtless this is due to the organism having accustomed itself to existing conditions. In any case, it is quite the opposite of the frequently observed phenomenon of an elevation of temperature up to as high as 41 C. (105.4 F.) in untrained persons who are working under conditions unsatisfactory for the loss of heat (for example, marching soldiers).

After the examinations had been made, the patient was followed for two years and a half. He reports that his sweat secretion has not returned and his symptoms are unchanged, being especially pronounced in the summer. He gets on better in life since the invalidity court had him trained in clerical work; he is now engaged in sedentary, inside work and is able to retain his capacity for work.

#### SUMMARY

A man with general anhidrosis, aged 27, until a long febrile illness (paratyphoid fever) six years prior to the examination had had normal sweat secretion. He

complained of extremely distressing symptoms under circumstances in which sweat secretion normally takes place. By means of a series of pharmacologic and physical tests I verified the patient's statement that he could not perspire.

A biopsy from the skin showed that about one half of the sweat glands were present while the other half had undergone degeneration.

By means of a number of muscular activity experiments it was determined that during increased heat production in the body the patient's heat regulation was normal but that signs of circulatory insufficiency arose which must be ascribed to extreme vascular dilatation in the skin. This forms the basis for a compensating, excessive loss of heat through conduction and radiation. Continued observations of the patient during two years and a half showed that the symptoms remain unchanged.

#### A LUMBAR PUNCTURE NEEDLE FOR THE ACCURATE CONTROL OF SPINAL FLUID FLOW

MARY MAZNER, M.D., New York  
Intern, Harlem Hospital

Any unnecessary and uncontrollable loss of spinal fluid while doing lumbar puncture for any purpose is undesirable. With the ordinary type of spinal tap needle the stylet has to be withdrawn completely to obtain spinal fluid or to make a spinal fluid pressure determination; and, to stop the flow, the stylet has to be reintroduced. This often causes an appreciable loss of cerebrospinal fluid. Also, with the needles in common use, spinal fluid will often flow along the under surface of the needle

Fig. 1.—Appearance of needle.

for a variable distance before it drops into a collecting test tube or ampule, and in this way there is a spill. It occurred to me that it might be of advantage to attempt to prevent this loss of cerebrospinal fluid by designing a needle that would perhaps control more accurately the escape of cerebrospinal fluid.

The needle is the stereotyped lumbar puncture needle, to which an obliquely placed bar outlet has been added. A Luer

Fig. 2.—Section illustrating the mechanism.

type syringe will fit both outlets. This needle has an adjustable stylet, which it is not necessary to withdraw completely in order to obtain spinal fluid. On the horizontal bar of the handle there is a set screw, which, when properly adjusted, prevents the complete withdrawal of the stylet. Under these circumstances it permits spinal fluid to flow from the opening in the oblique bar. The stylet is beveled so that complete withdrawal is impossible when the screw is set, but a turn of the screw

From the Surgical Service of Harlem Hospital, Dr. C. S. B. Cassano, director.

cury will produce diuresis.<sup>11</sup> These observations with regard to the concentration of chloride and sodium in the plasma and serum respectively indicate that some substances must have an optimal concentration in the plasma or serum and probably in other tissues, before renal action can occur. In renal edema, mercury appears to have a combined action; that is, it affects both the kidneys and other tissues. There is almost unanimous agreement that the renal action of mercury is attributable to a specific effect on the cells of the renal tubules, which leads to inhibition of tubular absorption of water and chlorides.

**Clinical Results.**—Since the introduction of merbaphen as a diuretic in 1920, it has been used in many types of edema, and the results often have been satisfactory. The clinical results obtained in 200 cases at the Mayo Clinic by a group of workers, including myself,<sup>12</sup> are submitted as typical of those secured by many physicians in different institutions. The control of diet and fluid intake is very important.<sup>13</sup> We employed compounds of organic mercury alone or in combination with other diuretic substances. These patients had cardiac disease, hepatic disease, renal disease, chronic lipid nephrosis, polyserositis, myxedema, intra-abdominal malignant disease with ascites, and general edema of indeterminate etiology. De Takáts<sup>14</sup> has reported that good diuretic action followed the administration of a mercurial compound in cases in which edema was attributable to thrombophlebitis. The diuretic results in our series of cases and in cases reported by others were most satisfactory in cardiac disease. A decrease of from 50 to 80 pounds (22.7 to 36.3 Kg.) not infrequently occurred.<sup>15</sup> The diuresis which follows the administration of mercurial compounds is usually much more satisfactory than that which follows the administration of digitalis or compounds of caffeine. When the dependent edema is excessive, it increases the load on the heart muscle so that early use of an organic preparation of mercury as a diuretic is indicated. Diuresis thus helps to restore myocardial function. The results of the administration of mercurial compounds in cases of lipid nephrosis were often as good as they were in cardiac disease. The effects in hepatic disease, particularly cirrhosis with ascites, were not so good as they were in the two previously mentioned conditions, although they compared favorably with the results obtained in cases of chronic glomerulonephritis with edema. The immediate results in myxedema were satisfactory. Both the temporary and the permanent effects obtained in a small group of cases of indeterminate ascites and edema were surprisingly good. The general consensus seems to be that, given a case of refractory edema, the therapeutic test with organic mercury should be considered.

**Dose and Toxicity.**—It has been the usual procedure to inject intravenously 0.5 cc. of a given compound of organic mercury as an initial trial dose. If no toxic effects are evident, 2 cc. is injected every three or four days as long as there is a distinct diuretic response. If diuresis does not occur after two or three injections,

other diuretics should be tried. Patients who have chronic edema have been given repeated doses of organic mercury for several years with beneficial action. The case reports of Wiseman,<sup>16</sup> Smith,<sup>17</sup> and Maxwell, Scott and Harvey<sup>18</sup> are pertinent in this connection. The latter gave 240 cc. (198 injections) of mersalyl to a patient with recurring cardiac edema, in five years. At necropsy, no renal disease was found. These authors advised a dose of 1.2 cc. of mersalyl for repeated injections for a prolonged period. Organic mercury, when given by mouth, has not proved satisfactory. There have been several reports, including that of Fulton,<sup>19</sup> of good action following the rectal administration of organic mercury. The lethal dose of mercury in the form of bichloride and merbaphen has been estimated for rabbits.<sup>20</sup> It varies from 2.5 to 5 mg. of mercury for each kilogram of body weight. The maximal dose tolerated by the rabbit is 3 mg. for each kilogram of body weight, and Keith and Johnstone<sup>21</sup> demonstrated that a similar amount is tolerated by the dog. Applying this dose to an adult human being who weighs 70 Kg., the theoretical dose that could be tolerated by a human being would be 6 cc. of merbaphen, a dose that is three times greater than the usual injected.

The distressing reactions that have actually been seen after the injection of organic mercury are stomatitis, diffuse dermatitis, diarrhea, hematuria and renal insufficiency. Luckily, these reactions are rare. They occurred more frequently after administration of merbaphen than they did after the administration of mersalyl. If administration of the drug was discontinued for from seven to ten days, the drug often could be administered again and would produce satisfactory effects. Mersalyl, in my hands, has been more toxic locally than has merbaphen. Wood,<sup>22</sup> on the other hand, had the opposite experience and found that merbaphen was more toxic locally. Sloughs are likely to occur in obese, edematous patients, who often have small peripheral veins, so that the injecting needle enters the lumen with difficulty. Dilution of mersalyl or merbaphen in 0.9 per cent solution of sodium chloride or in the patient's own serum should prevent such local sloughs in most cases. Melville and Steble<sup>6</sup> performed experiments on dogs, in order to compare the diuretic effects of mercury bichloride and organic mercury. They dissolved the former drug in an excess of the dog's own serum and found that the injection did not produce any local or general untoward reaction. He recalled Lister's<sup>23</sup> experiments, which were carried out in 1884 and which showed that mercury bichloride was soluble in an excess of horse serum and that it still had antiseptic properties in such a solution.

## ACID-PRODUCING SALTS

Since the introduction of calcium chloride as a diuretic by Schultz<sup>24</sup> in 1918, several other acid-producing salts have been used and accepted as having diuretic properties. These include ammonium chloride<sup>25</sup> and ammonium nitrate.<sup>26</sup> The diuretic action of these salts depends on the administration of a comparatively large dose and on the liberation of the acid radical within the body. For example, in the intestine, calcium chloride is split; the calcium in large part remains there unabsorbed, while the chloride readily passes through the intestinal wall. In the case of ammonium salts, which are readily absorbed, the ammonia is soon converted into urea and the acid radical liberated. The diuretic action of acid-producing salts is thought by many investigators to be caused by the shift in the acid-base equilibrium to the acid side. I believe there are additional factors, including a specific effect of the individual acid radical. The nitrate radical appears to have the most marked diuretic effect of the acids so far studied. The chloride radical produces the most marked shift in the acid-base balance toward the acid side and is particularly helpful in clinical cases of edema in which the value for chloride in the plasma is abnormally reduced; however, severe acidosis has occurred, and this fact must be kept constantly in mind when giving large daily doses of ammonium chloride. Methemoglobinemia may develop after the administration of ammonium nitrate<sup>27</sup> but soon disappears if the administration of the salt is promptly discontinued. Both ammonium chloride and ammonium nitrate may give rise to a moderate degree of renal insufficiency.<sup>12</sup> This effect is usually temporary. Evidence from different sources seems to indicate that the change in acid base balance to a more acid condition is the cause of the decrease in renal function. If severe renal insufficiency exists before these two salts are administered, their ingestion may give rise to retention of nitrates or to chloride acidosis, with their accompanying toxic symptoms. The administration of these salts is contraindicated when the value for the urea is 75 mg. or more per hundred cubic centimeters of blood.

The daily doses recommended for diuretic purposes are as follows: calcium chloride, 10 Gm.; ammonium chloride, 9 Gm.; ammonium nitrate, 12 Gm.; these doses are much larger than usually recommended and mentioned in the Pharmacopeia. Ammonium chloride and ammonium nitrate in my experience are best administered in doses of 0.5 Gm. as enteric coated pills.

## POTASSIUM SALTS

For two centuries, certain potassium salts have been employed as diuretics in clinical medicine. Wilks and Taylor<sup>28</sup> used potassium nitrate successfully in the treatment of dropsy in 1863. In 1920 Blum<sup>29</sup> and

Magnus-Levy<sup>30</sup> and Barker<sup>31</sup> in 1932 were able to show that potassium chloride could be administered safely by mouth in relatively large doses and that it frequently produced a satisfactory diuresis. It occurred to me in 1932 that potassium nitrate might be the salt of choice if potassium itself should have an additional diuretic action to the diuretic action of the nitrate radical. Since then I have been able to show that, when ingested by mouth, potassium salts, including the chloride, nitrate, bicarbonate, acetate and citrate, have a greater or lesser diuretic effect when administered to normal men.<sup>32</sup> After administration of each of these salts there was an increase in volume of urine and a rapid and efficient excretion of potassium in the urine. In fact the kidney was able to concentrate the potassium delivered to it by the blood serum approximately fifty times. Lack of absorption by the renal tubules is the most plausible explanation of this concentration of potassium. The reaction of the urine invariably became more alkaline, and after administration of potassium bicarbonate, potassium acetate or potassium citrate the  $p_H$  of the urine approached 8.0, a value that had been obtained previously after administering large amounts of similar salts of sodium. Potassium nitrate caused a relatively greater diuresis and greater increase in the excretion of chloride and sodium than did any of the other salts. Potassium chloride was next in efficiency, and still less efficient were potassium bicarbonate, potassium acetate and potassium citrate. Binger and I<sup>32</sup> administered potassium salts to a series of sixty patients who had edema that was attributable to various factors. Potassium nitrate was the salt of choice, although the chloride was administered to several patients and the bicarbonate was given to one patient. The diuretic results were very satisfactory in 50 per cent and fair in 33 per cent of cases; no diuretic action was noted in 18 per cent of cases. An increased urinary output was thus obtained in approximately 80 per cent of the cases.

To avoid toxic effects in cases of cardiac edema, Magnus-Levy<sup>30</sup> and Blum<sup>29</sup> advised giving small initial doses of potassium chloride. This has also been our procedure at the clinic in cases of edema in which there is severe renal insufficiency. However, in cases of renal dropsy in which there is extreme oliguria or anuria, or a value for the urea that is greater than 100 mg. per hundred cubic centimeters of blood, potassium salts should not be administered. In one case a concentration of 100 mg. of urea per hundred cubic centimeters of blood did not prevent a satisfactory diuresis. My results with the administration of potassium nitrate in cases of renal edema appear to be better than those obtained with ammonium nitrate. This may be attributable to the rapid excretion of potassium and to the shift in acid-base balance to the alkaline side. Since the preceding precautions were adopted at the clinic four years ago, we have not observed an unmistakable toxic effect that was attributable to the potassium radical.

The amount of a given salt necessary to produce diuresis is considerably greater than the dose recommended in the Pharmacopeia. The usual initial daily dose of potassium chloride was 9 Gm., and that for the nitrate and the bicarbonate was 12 Gm. Some patients

were able to take a 10 per cent solution of a salt without discomfort. Others complained of epigastric discomfort or even complained of nausea. Administration of the nitrate or the chloride in doses of 0.5 mg., in the form of an enteric coated pill, has been most satisfactory. This corresponds with our previous experience with the administration of ammonium chloride and ammonium nitrate.

#### CAFFEINE OR PURINE DIURETICS

Caffeine has been recognized as a diuretic in cases of dropsy since 1840, but it was not until von Schroeder<sup>33</sup> in 1887 performed his classic experiments, which demonstrated the effect of caffeine in normal rabbits and pigeons, that there was a scientific basis for its diuretic action. He demonstrated that caffeine with sodium benzoate increased both the volume and the solid constituents of the urine. He believed that its action was chiefly attributable to a direct renal effect. Since von Schroeder's work, numerous investigators have shown that the increased urinary excretion of solids was attributable to chlorides and fixed base, the latter being usually sodium.

The renal action of caffeine has been a subject of much research. Richards and Plant<sup>34</sup> and Cushny and Lambie<sup>35</sup> showed conclusively with rabbits that caffeine could produce a diuresis at times when the renal blood flow is not increased. Recent experiments on non-anesthetized rabbits by Walker, Schmidt, Elsom and Johnston<sup>36</sup> confirmed this observation. Richards<sup>37</sup> observations that caffeine causes an increased capillary flow in the glomeruli of the frog may mean that there is increased capillary permeability. Recent advances in renal physiology suggest that different types of diuretics might have specific actions on the glomeruli or the tubules. Schmitz<sup>38</sup> by employing the creatinine clearance test, was able to show that merbaphen and aminophylline had a different effect on renal excretion of creatine. Herrmann and associates obtained similar results clinically in cases of cardiac edema. Because there is some question as to the exact significance of creatinine clearance by the kidney, I do not feel that the results of Schmitz<sup>38</sup> and of Herrmann and his associates<sup>39</sup> have yet established the fact that aminophylline exerts its diuretic effect by increasing glomerular excretion. Perhaps, after all, von Schroeder's direct renal action may be attributable to the effect of caffeine on the cells of the renal tubules.

Several facts have indicated that extrarenal action may play a very important rôle in diuresis produced by caffeine. Curtis<sup>40</sup> has shown that caffeine diuresis is accompanied by slight but definite rise in total chlorides in the blood. He also cited experiments on rabbits in which the diuresis was inhibited by the intraperitoneal injection of distilled water and hypotonic solutions of sugar.

Meinertz in 1904<sup>41</sup> was the first to show by carefully controlled experiments on patients that administration of theobromine caused an increased excretion of chlorides as well as of water. Since then theophylline, aminophylline, and other xanthine compounds have been used both experimentally and clinically, with similar results. Two normal men whose intake of fluids and diet was controlled, as it was in our observations of the action of potassium salts, were given aminophylline. This produced a slight transitory increase in urine volume and urinary excretion of chlorides.<sup>7</sup> These compounds of caffeine were given to patients who have dropsy and have produced marked diuresis. The diuretic effects are neither so great, so rapid nor so uniform as are the effects of organic mercury. According to most workers, the present usefulness of these xanthine derivatives, alone or in combination with other diuretics, has been chiefly in cases of edema with severe renal insufficiency; in such cases these derivatives may produce satisfactory diuresis without any apparent toxic effect.

The xanthine diuretics employed clinically are theobromine with sodium salicylate, which is given in doses of from 3 to 4 Gm. daily; theophylline, which is given in doses of 1 Gm. daily; theophylline with ethylenediamine (aminophylline), which is given daily in doses of from 0.8 to 1 Gm. by mouth or intravenously in solution, and theophylline with sodium acetate (theocin), which is given in doses of 0.8 Gm. daily. All four preparations, if given continuously for some time by mouth, are likely to give rise to nausea and vomiting. A newer compound, in which sodium is replaced by calcium, namely, theobromine calcium salicylate (theocalcin), appears less likely to cause gastro-intestinal disturbances.

#### USE OF COMBINED DIURETICS

The use of diuretic mixtures is an old therapeutic principle in the treatment of dropsy. A frequently prescribed combination was digitalis, squills and mercury, but the results were often disappointing because of inadequate dosage. In 1924 and 1925 Whelan, Barrier and I<sup>42</sup> employed this principle in the treatment of edema and found that ammonium chloride and the compounds of organic mercury were much more effective when used in combination than they were when used singly. Later, Jacobs and I<sup>43</sup> substituted ammonium nitrate for ammonium chloride, as the former caused less digestive disturbances and possessed greater diuretic properties. Our clinical and experimental studies on the combined action of ammonium nitrate and compounds of organic mercury demonstrated that both types of substances, that is, an acid-forming salt and mercury, have the same fundamental property of removing water, chlorides and fixed base from the organism. The combined action was therefore suggested as a simple cumulative effect of the two substances. Blumgart and his associates<sup>44</sup> also considered that their results demonstrated such an additive effect. Ethridge, Myers and Fulton<sup>45</sup> have lately reported a thorough experimental study of this problem in dogs. Their results show clearly that in

dogs the combined effect of salyrgan and an acid-forming salt is greater than the sum of the effect of each when administered separately and therefore is not simply a cumulative effect. They found a constant decrease in the carbon dioxide combining power of the blood plasma of from 9 to 15 volumes per cent and suggested that this change in acid-base balance was the cause of the diuresis. I think that these changes in the plasma are too slight to account entirely for the diuresis and I believe that there are other etiologic factors, such as the specific effects of the individual acid ions, which must be considered. Further studies are needed to clarify the complicated equilibriums involved.

The combined use of diuretics has a distinct place in the present-day treatment of dropsy. The study of 200 cases of various types of edema, which was mentioned previously, showed how frequently the edema could be controlled. The best results were obtained when from 20 to 30 Gm. of such acid-producing salts, as calcium chloride, ammonium chloride and ammonium nitrate, or when such salts as potassium nitrate and potassium chloride were administered before the organic mercury was injected intravenously. The administration of larger doses of diuretic substances in part is responsible for these results, but physicians should be on the alert for the possible development of untoward reactions. In my opinion, toxic effects are becoming less frequent and, as our knowledge increases, they will become fewer. For example, since potassium nitrate and potassium chloride have been substituted for the ammonium salts, when employed either alone or combined with organic mercury, evidence of acidosis and increased renal insufficiency has almost disappeared. The favorable clinical reports of the action of a substance containing both the caffeine derivative theophylline and organic mercury indicate the future possibilities of combined diuretics.<sup>44</sup>

## Council on Foods

THE COMMITTEE HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT. FRANKLIN C. BING, Secretary.

The Council on Foods of the American Medical Association records with deep sorrow the death of

### EDWIN OAKES JORDAN

When Dr. Edwin Oakes Jordan died of cerebral thrombosis at the age of 70, the University of Chicago lost an honored professor emeritus of bacteriology, the medical sciences an outstanding investigator and the Council on Foods a distinguished member. Professor Jordan was born in Thomaston, Maine, on July 28, 1866. He received his formal education at the Massachusetts Institute of Technology and at Clark University; the latter institution awarded him the degree of Doctor of Philosophy in 1892. In that year he was appointed associate in anatomy at the newly organized University of Chicago. He was made professor of bacteriology in 1907 and held this position until 1933, when he became professor emeritus.

44. Crawford, J. H., and McDaniel, W. S.: Some Observations on Mercurial Diuretics, *Ann. Int. Med.* 8:1266-1273 (April) 1935. Certain substances such as thyroid extract (Epstein, A. A.: Thyroid Therapy and Thyroid Tolerance in Chronic Nephrosis, *J. A. M. A.* 87:913-918 [Sept. 18] 1926), parathyroid extract (McCann, W. S.: Diuretic Action of Parathyroid Extract-Collip in Certain Edematous Patients, *ibid.* 90:249-253 [Jan. 28] 1928), compounds of bismuth (Stockton, A. B.: Bismuth Diuresis and the Blood and Urinary Changes Under Clinical Conditions, *Arch. Int. Med.* 50:142-149 [July] 1932; Mehrtens, H. G.: Hanzlik, P. J.; Marshall, D. C., and Brown, N. S.: Bismuth as a Diuretic, *J. A. M. A.* 91:223-225 [July 28] 1928) and hypertonic solutions of dextrose and sucrose, when used clinically, have been found to produce diuresis. Their use has not been general, and lack of space does not permit detailed comment in this article.

Professor Jordan's early work was in biology; his doctoral dissertation was entitled "The Habits and Development of the Nemat." But early in his career when a student of Professor Sedgwick he became interested in bacteriology and gradually devoted more time to investigations in this field. In 1896 he studied at the Pasteur Institute. It was as an established bacteriologist that in 1900 he published an important paper on the bacterial self purification of streams. This now classic contribution represents work undertaken at the request of the Sanitary District of Chicago and carried out with E. E. Irons, who assisted him in making observations. Dr. Jordan determined bacterial counts on water from various locations along the drainage system of Chicago, particularly from Bridgeport southward along the Illinois River to the junction of the latter with the Mississippi above St. Louis. The results showed conclusively that the number of bacteria becomes less as one examines water samples farther and farther away from the source of contamination.

Dr. Jordan thus contributed at an early stage of his career to the solution of important questions of public health. He investigated the relationship between typhoid fever and contaminated water supplies, and he reported on the longevity of typhoid bacilli in sewage. This and similar work contributed largely to the development of "Standard Methods for the Examination of Water and Sewage" of the American Public Health Association. Professor Jordan's interest in the epidemiology of paratyphoid infections persisted throughout his entire career; it may be said that beginning in 1913 he was mainly responsible for the annual reports which have appeared in *THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION* on typhoid mortality in large cities in the United States. His work in epidemiology was not limited, however, to the study of the typhoid group of organisms. He is the author of at least a dozen papers on the epidemiology of influenza and other respiratory diseases.

He contributed much to our knowledge of bacterial morphology; possibly his early training in the structural aspects of biology may have been responsible for his interest in this important field. Specifically he should be credited with important observations on variations in bacteria and with the development of practical methods that are now used to differentiate the paratyphoid-enteritidis group of organisms.

Perhaps Dr. Jordan is best known for his fundamental contributions to the epidemiology of food poisoning, particularly that of bacterial origin. His monograph on "Food Poisoning and Food Borne Infection" is a classic in this special field. The importance of staphylococci as a source of food poisoning was emphasized in conjunction with G. M. Dack. In collaboration with associates, Professor Jordan showed that staphylococci are capable of producing an exotoxin which, if introduced orally, is capable of causing severe intestinal disturbance; the toxin is destroyed by boiling.

Dr. Jordan will be long remembered as a teacher, and as author and co-author of important textbooks. Since the organization of the Department of Hygiene and Bacteriology of the University of Chicago in 1913, approximately sixty students have taken their doctorate work in that department. The majority carried out the research for their dissertations under Dr. Jordan's immediate direction. The list of distinguished investigators who began their work in his laboratory—and this includes many who did not complete the work for the degree of Ph.D. in this field—is imposing. These men and women and others who were fortunate enough to come under the influence of Professor Jordan will always remember him as an earnest, scholarly investigator and as a courteous and kindly adviser. Many other persons will remember him as a gifted writer in the many fields to which he so richly contributed.

In his later years Dr. Jordan was called on to serve on innumerable boards and committees. He was elected a member of the Council on Foods in 1933. He was a member of many scientific and medical societies and was honored in the spring of 1936 by election to membership in the National Academy of Sciences. Because of his ability to concentrate on the fundamental principles and essentials of each task he was able to accomplish a prodigious amount of work. In the words of Ludvig Hektoen, "the results of his work stand well the tests of time."

## GASTRIC ACIDITY AND EXPERIMENTAL ULCER

The view that ulcers of the gastro-intestinal tract are due to a local loss of resistance on the part of the mucosa to the digestive activity of the gastric juice has been prominent since the time of John Hunter, more than 150 years ago. Indeed, the term "peptic" ulcer itself is an expression of that view. Theories to explain the local loss of resistance have been many. In general, as has been pointed out,<sup>1</sup> these have been concerned with a lowering of the normal resistance alleged to be conferred on the mucosa by such factors as a general "vital" principle, the protective action of gastric mucus, the neutralizing effect of alkaline blood in the capillaries of the mucosa, or the presence of an antipepsin in the mucosa. Recent studies, however, have tended to emphasize the immediate importance of a positive factor; namely, an increase in the amount of or activity of some corrosive agent in the gastric juice. The constant observation that ulcers occur only in those parts of the alimentary tract exposed to gastric juice, namely, the lower part of the esophagus, the stomach, the first part of the duodenum, the jejunum adjacent to the stoma of a gastro-enterostomy and the ileum adjacent to the entrance of Meckel's diverticulum, which contains a gastric type of mucosa, lends some support to this view.

Perhaps the most convincing evidence that an excessive amount of some constituent of the gastric juice is a primary etiologic factor in ulcers of the gastro-intestinal tract has come from a series of experiments, chiefly at the Mayo Clinic<sup>2</sup> and at the University of Chicago,<sup>1</sup> involving surgical alterations of the alimentary tract of the dog. Investigations in the former laboratories<sup>2</sup> demonstrated that ulcers in the jejunum almost invariably occurred in dogs in which this portion of the intestinal tract was anastomosed to the stomach and the duodenum was drained into the ileum. The

ulcers usually occurred near the line of the anastomosis. Since ulcer formation could be prevented by draining the duodenal secretions into the jejunum near the anastomosis, the conclusion that the lesions were due to the absence of the neutralizing effect of the duodenal secretions appeared warranted. Further evidence that high gastric acidity is a primary factor in the production of experimental ulcer has been obtained in a series of interesting experiments by the Chicago investigators.<sup>1</sup> First it was shown that certain tissues, such as spleen, kidney and sections of the duodenum or other portions of the small intestine, implanted in "windows" of normal stomachs remained intact whereas similar transplants into openings made in isolated gastric pouches were promptly digested away. Obviously, the most important difference between the conditions of these two experiments is the fact that the implants in the normal stomach were exposed to the action of gastric contents whereas those in the isolated pouch were exposed to pure gastric juice. As is well known, the principal difference between gastric contents and pure gastric juice is the higher free acid content of the latter, since partial neutralization by food and regurgitated duodenal contents cannot occur in the isolated pouch. Even more convincing results were obtained by the production of lesions in the gastric mucosa itself. Chronic, progressive perforating ulcers were produced in the mucosa of isolated gastric pouches by mechanically preventing the prompt drainage of gastric juice and thus causing it to remain in contact with the gastric wall for unusually long periods. If generalization is warranted from results on living frog muscle,<sup>1</sup> the concentration of acid necessary for the digestion of living tissue is from 0.1 to 0.15 per cent. Within wide limits, the concentration of pepsin appears to be of no importance. Usually the amount of free acid present in pure gastric juice obtained from pouches exceeded the critical level required for the digestion of intact tissues.

Other recent work<sup>3</sup> likewise places special emphasis on the importance of the acid of gastric juice in the production of experimental ulcers in the dog. As others have observed, it was found that ulcers developed in the jejunum just below the point of anastomosis to the pylorus, if the duodenal secretions were drained into the lower ileum. However, if the duodenal fluid was drained into the jejunum a few inches below the point of the gastrojejunal anastomosis or into the stomach itself, ulcers did not occur. Analysis of the gastric contents in both instances showed that the acidity was less than that apparently required for the digestion of living tissue.

Although the foregoing results appear to warrant the conclusion that increased acidity is probably the primary etiologic factor in the production of experimental ulcer in dogs, it cannot yet be stated that this conclusion

2. Mann, F. C., and Williamson, C. S.: The Experimental Production of Peptic Ulcer, *Ann. Surg.* 77: 409 (April) 1923.

3. Wilhelmj, C. M.; O'Brien, F. T.; McCarthy, H. H., and Hill, F. C.: The Role of the Duodenal Secretions in the Prevention of Experimental Jejunal Ulcer, *Am. J. Physiol.* 117: 79 (Sept.) 1936.

applies to the disease occurring in man. However, as has been pointed out by Dragstedt,<sup>1</sup> the frequency of the occurrence of abnormally high gastric acidity in patients with gastric or duodenal ulcer indicates that the relationship may be more than casual.

### ANOREXIA NERVOSA

Sir William Gull in 1868 referred to "a peculiar form of disease occurring mostly in young women, and characterised by extreme emaciation." This condition, which involves a refusal to eat, has since become known as anorexia nervosa. Ryle,<sup>1</sup> in the Schorstein Memorial Lecture delivered at the London Hospital October 15, discussed the present state of knowledge of this disorder. His analysis was based on a personal experience of fifty-one cases seen during sixty-one years of consulting practice. "In common with other psychoneurotic disorders," he states, "the incidence is higher in the middle and upper classes. . . . Motive and opportunity and perpetuating causes are more frequent in homes where circumstances do not demand active physical occupation and where sensitive natures and solicitude flourish side by side." There was specific mention of nervous heredity in only nine cases in the whole series. These included one instance of a drunken parent and two instances of one insane parent. A closer inquiry would, he believes, reveal a far higher incidence of "nervousness" in the immediate family history of these cases. Of the initiating factors in the young women (who form the largest group affected), emotional crises in the shape of love affairs, broken engagements and possibly school attachments may be considered to be important. "Slimming," usually instigated by the ridicule of school friends on account of adolescent plumpness, is generally considered second in importance to these emotional crises. In several cases poorly conducted homes were largely to blame. In nine cases the anorexia seemed to develop on a basis of genuine physical illness or after an operation. The probability of multiple contributory factors, however, must be constantly considered.

The onset of the condition is usually insidious. The most pronounced clinical characters are loss of weight, poor appetite and amenorrhea. The important factors of the clinical examination are the prominence of the bones, the scaphoid abdomen and absence of anemia. There is a tendency to the development of excess hair on the body and face. The pulse is slow and the blood pressure is usually low. Organic disease cannot usually be discovered. The prognosis in the psychoneurotic group is generally good if diagnosis is not too long postponed and appropriate treatment is arranged. Complications may occur but are relatively rare. Evidences of deficiency disease are exceptional. Pulmonary tuberculosis may be superimposed and must always be thought of as a possible complication.

The first essential of treatment, Ryle believes, is to explain to the patient and the parents separately the nature of the disease in the simplest and most direct terms. Strong assurance is highly important. Firmness, kindness and tact must be employed in just proportions, and the dietary carefully watched. In some cases it may be necessary to sit with the patient until each meal is finished. Treatment should be started in bed and continued there until definite improvement can be noticed. Psychoanalytic methods he thinks are unwise and may do harm. Explanation, reassurance, distraction and fit treatment of the starvation are usually adequate. The key to real advancement, Ryle states, still lies largely with earlier diagnosis and rational preventive treatment.

### PATHOGENIC FUNGI

In a recent review on pathologic fungi<sup>1</sup> it is pointed out that there is at present a growing tendency to give increased attention to the etiologic relationship of such organisms to disease particularly of the ear, nose, throat and lower respiratory system. The author states that in the routine of a private practice he has observed seventeen patients with verified fungous infection of the ear, nose, throat and respiratory tract during the past twelve months. Vigilance is required, therefore, on the part of practicing physicians for the detection of patients affected by such infestations.

Clinical reports relating certain species of fungi to disease are numerous. The yeastlike fungus *Monilia*, for example, is known to produce a group of conditions, known as moniliasis, involving the skin, mucous membranes and viscera. This type of fungus produces distinct lesions of the oral and pharyngeal cavities (thrush) and even of the bronchopulmonary system. Pulmonary moniliasis may be accompanied by symptoms which simulate those of pulmonary tuberculosis. Indeed, the clinical picture of severe pulmonary moniliasis is that of advanced tuberculosis, there being a cough, expectoration, hemoptysis, septic fever, night sweats and emaciation. A positive diagnosis of the disease may be established by the constant finding of *Monilia* in the sputum. Likewise, certain species of the genus *Sporotrichum* are known to be pathogenic to man. These may produce granulomatous processes, termed sporotrichosis, in the skin and mucous membranes and in the bronchopulmonary and other systems of the body. Also certain species of *Blastomyces*, *Actinomyces* and *Aspergillus* are included among the different types of fungi reported to be pathogenic to man, the disease processes again involving particularly the ear, nose, throat and respiratory tract.

Because of the increasing numbers of reported occurrences of fungous infections in man, Whalen<sup>1</sup> has out-

1. Ryle, J. A.: Anorexia Nervosa, *Lancet* 2: 893 (Oct. 17) 1936.

1. Whalen, E. J.: Pathogenic Fungi, *Arch. Otolaryng.* 21: 436 (Oct.) 1936.

lined procedures for the simple and rapid examination of material suspected to contain any of the more common types of pathogenic fungi. He provides also a discussion of some of the accepted methods of treatment of these diseases. Obviously, the determination of the identity of the causative fungus is necessary to a correct diagnosis and the successful treatment of the disease.

## Current Comment

### THE NEW BULLETIN

As was noted in a recent issue of *THE JOURNAL*, the Board of Trustees of the American Medical Association has decided to conclude publication of the *American Medical Association Bulletin* with the issue for December 1936 and to substitute for it a special publication, the first issue of which will appear with *THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION*, Jan. 2, 1937. The new publication is to be known as the *Bulletin of the American Medical Association*. It will comprise approximately eight pages in each issue and will be published as a part of *THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION* each week. The new publication is to be devoted to the economic, business, organizational and social aspects of medical practice. Among early features already scheduled are a series of articles describing the headquarters office of the American Medical Association and the work of the various departments; a series of articles on rural medical service in the United States, discussing this service as a whole as well as by individual states; a considerable amount of material describing new forms of medical practice in various parts of the country, and also official announcements and bulletins relative to the work of various committees, councils and official bodies of the Association. One section of the *Bulletin* will be devoted to the Woman's Auxiliary. The *Bulletin* will be edited as a part of *THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION*. Those desiring to submit manuscripts dealing with the phases of medicine here mentioned may submit them to the *Bulletin*. It is proposed also to feature as a part of this publication a history of the American Medical Association, to be published serially, and the results of much of the work of the Bureau of Medical Economics.

### THE ATLANTIC CITY SESSION—1937

The annual session of the American Medical Association that was held in Atlantic City in 1935 was no doubt the best attended medical meeting ever held anywhere in the world. More than 8,400 physicians registered and the complete registration, including the wives of physicians, exhibitors and others taking part in the session, might well have made the attendance exceed 12,000. Now the Association is scheduled to return to Atlantic City for its annual session in 1937. The Council on Scientific Assembly, the chairmen and the secretaries of the various sections and officers of the Association met in the headquarters office in Chicago recently to consider some of the plans for this meeting.

The prospects already indicate a session notable in many different ways. The invited guests include physicians from various foreign countries conspicuous for their contributions to the advancement of medical science. The officers of the various sections have been besieged by applicants for places on the programs. The Scientific Exhibit is also in receipt of great numbers of applications and there will be subsidized exhibits on anesthesia and on fractures. The Council on Scientific Assembly has arranged for several general sessions, which will include clinical demonstrations, graduate lectures, talking motion pictures, and a special general assembly on the subject of the diagnosis and treatment of syphilis. The session will, moreover, be replete with entertainment which only a place like Atlantic City can provide.

### THE CENTENNIAL OF EMORY UNIVERSITY

The November issue of the *Journal of the Medical Association of Georgia* is devoted to the commemoration of the School of Medicine of Emory University and its direct predecessors. The charter for the Atlanta Medical College, which eventually became the Emory University School of Medicine, was granted by the legislature in 1854. After a somewhat stormy career, characteristic of many of the early medical colleges in this country, the entire holdings of the Atlanta Medical College were deeded to Emory University on June 15, 1915. Since that time the medical department has functioned as an integral part of the university. The history as well as the present high-ranking nature of the departments of the School of Medicine, as recorded in this issue of the *Journal of the Medical Association of Georgia*, furnishes stimulating reading and is characteristic of many of the finer medical developments in this country.

### PRODUCTION OF IODINE

Despite the recognition that iodine is indispensable to physiologic well being, that it plays a part in therapeutics and that it finds important use in industry, it is more or less surprising that little of this important element was produced in the United States prior to 1932. This country was dependent on a foreign monopoly for its supply. During the World War attempts were made to make iodine by the extraction of seaweed, but the quantities produced were small and this type of manufacture has been largely discontinued. A recent comment<sup>1</sup> on a report of the Chemical Division of the Department of Commerce indicates that this country has recently assumed a leading position in the production of iodine. During 1935 the sale of this element by producers amounted to 245,700 pounds, and for the past four years it has averaged 276,500 pounds annually. The source of the iodine is salt brine and the waters from oil wells, the most successful projects being located in California. This rapid industrial chemical development has raised the United States from an essentially dependent nation as concerns iodine to the world's second largest producer.

## Association News

### RADIO BROADCASTS

The American Medical Association and the National Broadcasting Company are presenting the second series of dramatized health broadcasts under the title *Your Health*. The first broadcast in the new series, the thirty-second dramatized cooperative broadcast under the title *Your Health*, was given October 13. The theme for 1936-1937 differs slightly from the topic in the first series, which was "medical emergencies and how they are met." The new series is built around the central idea that "100,000 American physicians in great cities and tiny villages, who are members of the American Medical Association and of county and state medical societies, stand ready, day and night, to serve American people in sickness and in health."

The program will go out on the Blue network instead of on the Red network, as originally announced.

The topics are announced monthly in advance in *Hygeia*, the Health Magazine, and three weeks in advance in each issue of *THE JOURNAL*. The topics and speakers for the next three programs are:

December 22. The Gift of Health. Morris Fishbein, M.D.  
December 29. Health Assets and Liabilities. W. W. Bauer, M.D.  
January 5. "Smog." W. W. Bauer, M.D.

The time of the broadcast is Tuesday afternoon at 4 o'clock central standard time (5 o'clock eastern time, 3 o'clock mountain time, 2 o'clock Pacific time).

## Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST; SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

### ALABAMA

**Dr. McLester Appointed Professor of Medicine.**—Dr. James S. McLester, Birmingham, has been named professor of medicine at the University of Alabama School of Medicine. He is an alumnus of the university, class of 1896, and a recent Past President of the American Medical Association. Other promotions include:

Dr. John Howard Ferguson to associate professor of physiology and pharmacology.  
Albert S. Harris, Ph.D., assistant professor of physiology and pharmacology.  
Dr. Edgar Gilmore Givhan Jr., associate clinical professor of medicine.  
Dr. James B. McLester, associate clinical professor of medicine.

### ARIZONA

**Annual Registration Due January 1.**—Every person practicing medicine, surgery or osteopathy in Arizona is required by law to pay annually on or before January 1, to the board of medical examiners, a renewal license fee of \$3. Any licensee who does not renew his license as required above is to be penalized \$1 for each day that he practices without a renewal license, not to exceed \$50. The board of medical examiners is to revoke the license of any licensee who fails to renew his license for three successive years.

### CALIFORNIA

**New Mental Hospital Unit.**—The first unit of a new hospital for mental disease at Camarillo, Ventura County, was formally opened October 12. The group of buildings, including the men's unit, was constructed at a cost of \$1,380,000. When completed, the institution will have cost \$7,000,000. The women's unit is the next section to be erected. There are now 160 patients in the hospital.

**Society News.**—The Los Angeles County Medical Association has organized a speakers' bureau. At a meeting of the council of the society, November 2, the plan to obtain a copy of the bust of Dr. Joseph P. Widney, owned by the University of Southern California Medical School, was approved; it will be placed in the association's building. A plan to have members of the society use the words "Member—L. A. County Medical Assn." under their names on their office doors was also approved.—Dr. Otto Barkan, San Fran-

cisco, discussed "An Operation for Chronic Glaucoma" before the Los Angeles Society of Ophthalmology and Otolaryngology, November 30.—Dr. Edmund W. Butler, San Francisco, addressed the Sacramento Society for Medical Improvement recently on diagnosis and treatment of injuries of the chest and abdomen.—At a meeting of the San Bernardino County Medical Society in San Bernardino, October 6, the program was devoted to presentations by "Pioneers of Medicine in the San Bernardino Valley"; Drs. Thomas M. Blythe, Redlands, licensed in 1888; Marie A. Bennette, San Bernardino, 1886; Joseph A. Champion, Colton, 1895; John N. Baylis, San Bernardino, 1887, and William A. George, Loma Linda, 1911.—A recent meeting of the San Joaquin County Medical Society was addressed, among others, by Dr. Laurence R. Taussig, San Francisco, on "Common Skin Diseases and Their Treatment."—At a meeting of the Tulare County Medical Society in Visalia, September 6, Dr. Theodore L. Althausen, San Francisco, discussed "Recent Advances in Diagnosis and Treatment of Gallbladder Disease."

### COLORADO

**Society News.**—The Northeast Colorado Medical Society was addressed at a meeting in Sterling, November 12, by Drs. George P. Lingenfelter, Charles B. Kingry and Sanford Withers, the state society's cancer team, on "Clinical Diagnosis of Early Cancer." All are from Denver.—At a meeting of the Pueblo County Medical Society, November 17, in Pueblo, Dr. Herman Schwatt, Spivak, discussed "Collapse Therapy in Tuberculosis."

### CONNECTICUT

**Dental Program.**—The state department of health has instituted a dental program in the schools in an experimental area comprising eleven towns, including classroom talks, group instruction, individual examinations and prophylaxis. The work has been completed in three grades in four schools; a fifth is about to be completed, and the work is under way in two more. The program is an extension of the annual well child conferences and summer roundups and is planned to include health talks and the showing of films.

**Personal.**—Dr. Paul H. Brown, health officer of East Haven, has been appointed an epidemiologist in the bureau of communicable diseases, state department of health, on a part time basis; he succeeds Dr. John S. Cunningham, Hartford, who is on leave of absence for one year at the Harvard School of Public Health.—Dr. Wilmar M. Allen, recently appointed director of the Hartford Hospital, was guest of honor at a dinner given by members of the staff, November 5. Dr. Claude W. Munger, Valhalla, N. Y., president of the American Hospital Association, was guest speaker.

**Special Meeting on Pneumonia and Syphilis.**—The Connecticut Public Health Association held a meeting in Waterbury, December 16, to discuss pneumonia and syphilis. A symposium on pneumonia was held in the morning with Drs. Francis G. Blake and Joseph I. Linde, New Haven, and Alfred L. Burgdorf, Hartford, as the speakers, while the symposium on syphilis in the afternoon was presented by Drs. Raymond A. Vonderlehr, assistant surgeon general, U. S. Public Health Service; John L. Rice, health commissioner of New York; Maurice J. Strauss, New Haven; Karl T. Phillips, Putnam, and Henry P. Talbot, Hartford. Other speakers on the program included Drs. Millard Knowlton, Hartford, and Allan J. McLaughlin, U. S. Public Health Service. The session closed with a sound motion picture, "For All Our Sakes."

### DELAWARE

**Pathologic Conferences.**—A series of pathologic conferences opened at the Delaware Academy of Medicine, Wilmington, November 6, on diseases of the kidneys. The second was given December 4 on diseases of the gallbladder. Others in the series, which are of interest to practitioners in all branches of medicine and surgery, are: January 8, carcinoma of the lung; February 5, cardiovascular diseases, and March 5, diseases of the brain.

### DISTRICT OF COLUMBIA

**Dr. Cumming Receives Hartley Medal.**—Dr. Hugh S. Cumming, surgeon general, U. S. Public Health Service, retired, was presented with the Marcellus Hartley Gold Medal "for eminence in the application of science to the public welfare" at the annual meeting of the National Academy of Sciences, November 17, in Chicago. Dr. Cumming, now 67 years old, retired January 31 after sixteen consecutive years as surgeon

general. He had been identified with the service since 1894. He was president of the American Public Health Association in 1931.

**Personal.**—Dr. Earl B. McKinley, dean and professor of bacteriology, George Washington University School of Medicine, has been granted sabbatical leave for the second semester; he will leave in January for the Orient, where he will conduct research on leprosy under the auspices of the American Leprosy Foundation, formerly the Leonard Wood Memorial. Later, traveling around the world, Dr. McKinley will gather material concerning the geographic distribution of disease for inclusion in a volume, to follow one on the geography of disease, entitled "A Cartography of Disease," now in preparation under a grant from the Carnegie Institution of Washington, D. C. Dr. McKinley will return to Washington in September 1937.

**Annual Dinner of Smith-Reed-Russell Society.**—Dr. Charles Franklin Craig, professor of tropical medicine, Tulane University of Louisiana School of Medicine, New Orleans, gave the oration at the annual dinner of the Smith-Reed-Russell Society, George Washington University School of Medicine, Washington, November 17. His subject was "Factors Influencing the Transmission of Malaria." Dr. Ernest Muir, secretary-general of the International Leprosy Association, gave the second lecture in the Smith-Reed-Russell series for 1936 on this occasion, entitled "The Reaction of the Tissues to the Leprosy Organism." The first lecture in the series was delivered by Dr. Richard P. Stroug, professor of tropical medicine, Harvard University Medical School, Boston, on "The Parasitic and Bacillary Dysenteries."

## FLORIDA

**Annual Registration Due January 1.**—Every practitioner of medicine and surgery holding a license to practice in Florida is required by law to register annually on or before January 1, with the secretary of the state board of health, and at that time to pay a fee of \$1. A licensee failing to register annually is liable to a fine of not more than \$50.

**Society News.**—At a meeting of the DeSoto-Hardce-Highlands County Medical Society in Sebring, October 13, Drs. Spencer A. Folsom and Frank D. Gray, Orlando, discussed cardiac disease and renal denervation, respectively.—Dr. Turner Z. Cason discussed heart block before the Duval County Medical Society, October 6, in Jacksonville.—At a meeting of the Pinellas County Medical Society recently, Dr. Arnold S. Anderson, St. Petersburg, spoke on oxygen therapy.—Dr. Frederick Clifton Moore, Tallahassee, addressed the Suwannee River Medical Association, November 13, on "Indications and Limitations of Artificial Pneumothorax in the Treatment of Pulmonary Tuberculosis."

## ILLINOIS

**Society News.**—The Sangamon County Medical Society was addressed in Springfield, December 3, by Dr. Arthur Steindler, Iowa City, on "Low Back Pain: Contribution to Differential Diagnosis," and Hugh J. Graham Jr., J.D., "The Social Security Act."

### Chicago

**Window Exhibit.**—The present exhibit of the Chicago Medical Society in the Marshall Field and Company Annex Building is based on a recent report issued by the state department of health which showed that during the Christmas 1935 holidays the following cases in Illinois were in quarantine:

Smallpox .....	25	Whooping cough.....	851
Typhoid .....	27	Scarlet fever.....	2,451
Diphtheria .....	304		
		Total .....	3,622

The exhibit shows a child quarantined at home with scarlet fever, looking out at other children playing in the snow. Signs in the window say "This child was not protected" and a card by the children outdoors says "These children are protected; are yours?"—A poster printed in red and green says "Christmas Gifts for Children Should Include Immunization Against Contagious Diseases."

**Society News.**—Dr. Milton B. Cohen, Cleveland, discussed "The Importance of the Recognition of the Minor Allergies" before the Chicago Medical Society, December 2. Drs. Isidor Harrison Tumpcer and Harry L. Huber spoke on "Allergy in Childhood" and "General Treatment of Allergy" respectively.—At a meeting of the Chicago Surgical Society, December 4, the speakers included Drs. Henry N. Harkins on "Mesenteric Thrombosis" and Harry E. Mock, "Certain Intra-Abdominal Lesions Simulating Malignancy."—Dr. Heinrich Finkelstein, director, Municipal Children's Hospital, Berlin, Germany, addressed the Chicago Laryngological and Otological

Society, December 7, on "Mastoiditis in Infants."—Dr. Percy Starr Pelouze, Philadelphia, among others, discussed gonorrhea before the Chicago Urological Society, November 19.—Dr. William P. Healy, New York, addressed the Chicago Gynecological Society, December 18, on "The Use of Radium and X-Rays in Gynecology."

## IOWA

**Society News.**—At a meeting of the Cedar County Medical Society in Tipton, October 16, Drs. Fred M. Smith, Iowa City, discussed treatment of cardiac failure, and Arthur W. Erskine, Cedar Rapids, the cancer problem in Iowa.—Dr. A. Fred Watts, Creston, addressed the Dallas-Guthrie Counties Medical Society, October 15, in Panora, on infant feeding, and Dr. Carl E. Sampson, Creston, eye, ear, nose and throat conditions in general practice. Dr. John H. Peck, Oakdale, discussed the tuberculin reactions in his tests of various patients in the Panora schools at a luncheon meeting of the society and the woman's auxiliary.—The Fremont County Medical Society was addressed in Sidney, October 19, by Drs. Jack V. Treynor on immunization with special reference to scarlet fever and measles, and Karl R. Werndorff, Council Bluffs, different forms of Colles' fracture and the treatment.—Dr. Homer W. Scott, Fort Dodge, addressed the Hamilton County Medical Society in Webster City, October 26, on "Transurethral Prostatic Resection."—At a recent meeting of the Johnson County Medical Society, Oakdale, Dr. Everts A. Graham, St. Louis, discussed bronchogenic carcinoma.—The Montgomery County Medical Society was recently addressed in Red Oak by Drs. Jay C. Cooper, Villisca, on medical legislation, and Harold C. Bastron, Red Oak, lymphoid tissues of the nasopharynx.—A special scientific meeting of the Des Moines Academy of Medicine and the Polk County Medical Society was addressed, October 13, by Drs. Joseph A. Weinberg, Omaha, on bronchiectasis, and Harold E. Eggers, Omaha, experimental study of cancer.

## KANSAS

**Personal.**—Dr. Francis A. Carmichael, formerly superintendent of the Osawatimie State Hospital, has been appointed chief clinical adviser of the six state hospitals in Missouri; he will make his home in Fulton.—The Brown County Medical Society held a party in honor of Dr. Willard W. Nye, Hiawatha, September 26, celebrating his ninetieth birthday.—Dr. Henry J. Deaver, Sabetha, has been appointed health officer of Nemaha County, succeeding Dr. Frederick S. Deem, Oucida, who resigned to become physician for a CCC camp at Kingman.

**Society News.**—Dr. Peter T. Bohan, Kansas City, among others, addressed the Clay County Medical Society in Clay Center, October 14, on "Uses and Abuses of Internal Medicine."—A symposium on normal delivery was presented before the Coffey County Medical Society in Burlington, October 22, by Drs. John H. Rinehart, Lebo; Albert N. Gray, Burlington; Henry M. Benning, Waverly, and Hubert G. Her-ring, LeRoy.—At a joint dinner meeting of the Marion, Harvey and McPherson county medical societies, October 28, in Marion, Drs. Leroy A. Calkins, Kansas City, Mo., among others, spoke on "Cancer of the Cervix," and Vincent T. Williams, Kansas City, Mo., "The Abdominal Masquerades of Heart Disease."

## LOUISIANA

**Annual Renewal Due January 1.**—Every practitioner of medicine and surgery holding a certificate to practice in Louisiana is required by law to have his certificate renewed annually, on or before January 1, by the secretary-treasurer of the state board of medical examiners, and at that time to pay a fee of \$2. The board may by unanimous vote revoke any certificate not renewed.

**Health at New Orleans.**—Telegraphic reports to the U. S. Department of Commerce from eighty-six cities with a total population of 37 million, for the week ended December 5, indicate that the highest mortality rate (21.3) appeared for New Orleans and that the rate for the group of cities as a whole was 12.2. The mortality rate for New Orleans for the corresponding period last year was 19.4 and for the group of cities, 12.2. The annual rate for eighty-six cities for the forty-nine weeks of 1936 was 12 as against a rate of 11.3 for the corresponding period of the previous year. Caution should be used in the interpretation of these weekly figures, as they fluctuate widely. The fact that some cities are hospital centers for large areas outside the city limits or that they have a large Negro population may tend to increase the death rate.

## MASSACHUSETTS

**Medal to Dr. Sellards.**—The Laveran Gold Medal of the Société de pathologie exotique of Paris has been conferred on Dr. Andrew W. Sellards, associate professor of tropical medicine, Harvard University Medical School, Boston. Dr. Sellards has been associated with French investigators in the study of yellow fever since 1927. This work has culminated in the development of an effective vaccine, which has now been employed for the protection of more than 20,000 persons. Dr. Sellards first demonstrated that the virus of yellow fever could be preserved in vitro and transported, and in 1928 he brought the first strain from Africa, which was established at once in several laboratories in Europe, London, New York and Boston.

**Changes in the Faculty at Tufts.**—New appointments to the faculty of Tufts College Medical School, Boston, include those of Dr. John L. Jacobs as associate professor of bacteriology, and Drs. William E. Browne and Archibald McK. Fraser as clinical professors of surgery. The following promotions have been made on the faculty:

Dr. James J. Hepburn, professor of surgery to succeed Dr. Horace Wynne, now professor emeritus.

Dr. Benjamin Sachs, professor of ophthalmology, succeeding Dr. Edward K. Ellis, now professor emeritus.

Dr. James M. Baty, assistant professor of pediatrics.

Dr. Francis C. McDonald, assistant professor of pediatrics.

Dr. Arthur Berk, assistant professor of psychiatry.

Dr. Otto J. Hermann, clinical professor of surgery.

Dr. Harry H. Powers, Ph.D., assistant professor of biochemistry.

Dr. Louis A. O. Goddard, clinical professor of orthopedics.

Dr. Armin Klein, clinical professor of orthopedics.

Dr. John D. Adams, assistant professor of orthopedics.

Dr. Frederick W. Stetson has been made professor emeritus of medicine.

## MICHIGAN

**Memorial to Dr. Harison.**—A bronze tablet placed in the War Memorial Hospital, Sault Ste. Marie, in memory of the late Dr. Beverly Drake Harison, Detroit, contains the following inscription:

BEVERLY DRAKE HARISON  
1855-1925

PROMINENT SAULT STE. MARIE PHYSICIAN.  
FOREMOST WORKER IN MICHIGAN MEDICAL LEGISLATION.  
ONE OF THE FOUNDERS OF THE UPPER PENINSULA  
MEDICAL SOCIETY.

PRESIDENT OF THE MICHIGAN STATE MEDICAL  
SOCIETY IN 1904.

SECRETARY OF THE MICHIGAN STATE BOARD OF REGIS-  
TRATION IN MEDICINE FOR TWENTY-FOUR YEARS.

ERECTED BY THE MICHIGAN STATE MEDICAL SOCIETY  
AND THE CHIPPEWA COUNTY MEDICAL SOCIETY.

## NEBRASKA

**Society News.**—At a meeting of the Lancaster County Medical Society, October 20, the speakers were Drs. Edward W. Rowe and John Marshall Neely, Lincoln, on "Primary Malignancy of the Small Intestine" and Czar C. Johnson, Lincoln, on "The Healing Arts," a review of Nebraska medical laws.—The autumn meeting of the Third Councilor District Medical Society was held at Tecumseh, November 20, with the following speakers, all of Omaha: Drs. Charles W. McLaughlin Jr., on "Management of Peripheral Vascular Disease"; Olin J. Cameron, "A Practical Skin Clinic"; Frank Conlin, "Diabetic Complications"; David P. Findley, "Obstetric Analgesia and Anesthesia." Following a dinner Dr. Albert F. Tyler, Omaha, discussed "Treatment of Malignancies of the Face and Mouth" and Mr. M. C. Smith, executive secretary of the Nebraska State Medical Association, field activities of the association.—At a meeting of the Madison Six County Medical Society in Norfolk, November 17, the speakers were Drs. Abram E. Bennett, Omaha, on "Management of Psychoneurotic Patients in General Practice"; Theodore M. Barber, Norfolk, "A Review of Five Years of Musical Therapy at the Norfolk State Hospital," and Richard H. Young, Omaha, "Early Signs and Recent Advancement in the Treatment of Psychiatric States."

## NEW JERSEY

**Personal.**—Dr. Robert A. Kilduffe, Atlantic City, has been appointed editor of the *American Journal of Clinical Pathology* to succeed Dr. Thomas B. Magath, Rochester, Minn., who has served two three-year terms. The journal is the official organ of the American Society of Clinical Pathologists.—Dr. Clarence Garrabrant, Atlantic City, recently celebrated his fiftieth anniversary in the practice of medicine and his eightieth birthday.

**Society of School Physicians.**—The New Jersey Association of School Physicians was organized at a meeting in Newark, November 9, with Dr. Harry B. Silver, Newark, as president and Dr. Aaron H. Horland, Newark, as secretary. Objectives outlined are medical leadership in health education and service in the public schools, standardization of health services throughout the state, improvement in the health service rendered by school physicians, establishment of a special section for school physicians in the state and county societies, and to act as a clearing house for statistical data. The next meeting will be held at Atlantic City in conjunction with the annual meeting of the Medical Society of New Jersey in April 1937.

## NEW YORK

**Annual Registration Due January 1.**—Every practitioner of medicine and surgery in New York is required by law to apply annually, on or before January 1, to the secretary of the board of medical examiners for a certificate of registration, on application forms furnished by him, and to pay at that time a fee of \$2. The law authorizes the secretary of the board to permit secretaries of duly incorporated medical societies to act as his representatives, to receive and transmit to him such applications and fees. Practitioners are liable to severe penalties for failing to register and for continuing in practice thereafter.

**Society News.**—At a meeting of the Rensselaer County Medical Society, November 10, the speakers were Drs. Eugene F. Connally, on "Carcinoma of the Colon"; Irwin Johnston, "Diagnosis of Chronic Infections of the Tonsils in Relation to Indications for Operation in Cases of Focal Infection," and Leo S. Weinstein, "Chronic Osteomyelitis." All are from Troy.—Drs. Gordon D. Hoople and Frederick S. Wetherell, Syracuse, addressed the Syracuse Academy of Medicine, December 15, on "Bronchoscopic Diagnosis of Carcinoma of the Lung" and "What Surgery Can Do in Carcinoma of the Lung" respectively.—Dr. James E. King, Buffalo, addressed the Broome County Medical Society, Binghamton, December 8, on "Office Practice of Gynecology."

## New York City

**County Society Lecture Bureau.**—The Medical Society of the County of New York has formed a lecture bureau to provide speakers for lay organizations and is now developing a list of physicians who are willing to give addresses. Members of the committee in charge of the bureau are Drs. Clarence G. Bandler, Peter Irving and Alfred M. Hellman.

**Women Organize for Cancer Control Campaign.**—Representatives from seven Eastern states met in New York November 20 to organize the Women's Field Army, which is being sponsored by the American Society for the Control of Cancer in a campaign of education addressed to the public. "Commanders" from Maine, New Hampshire, Delaware, New York, Pennsylvania, Rhode Island and West Virginia heard addresses by Mrs. Grace Morrison Poole, national adviser to the movement, and Clarence C. Little, Sc.D., director of the American Society for the Control of Cancer. The drive will be continued till March 27, the last week being devoted to enlistment of women as volunteers. After that time the army will go on a permanent basis and will conduct an educational campaign the year round.

**Dr. Northrop Wins Chandler Medal.**—John Howard Northrop, Ph.D., of the Rockefeller Institute for Medical Research, Princeton, N. J., branch, has been awarded the Charles Frederick Chandler Medal of Columbia University for 1936, it was announced December 7, in recognition of fundamental discoveries concerning bacteria, the constitution of protein and the chemistry of digestion. He will deliver the Chandler Lecture in the spring. The medal was founded in 1910 in honor of Professor Chandler, who taught at Columbia and was a pioneer in industrial chemistry. Dr. Northrop, who studied under Professor Chandler, received the degree of doctor of philosophy in 1915 at Columbia and has been associated with the Rockefeller Institute since 1916. During the tercentenary celebration at Harvard University in September he received the honorary degree of doctor of science.

## NORTH CAROLINA

**District Meeting.**—The Eighth District Medical Society met at Leaksville, November 24, with the following speakers: Drs. Roscoe L. Wall, Winston-Salem, on "Cyclopropane-Avertin Anesthesia"; Merle D. Bonner, Jamestown, "Tuberculosis in Children"; Julian M. Ruffin, Durham, "Bloody Diarrhea—Etiology and Treatment"; James F. Marshall, Winston-Salem, "Gynecologic Aspects of Backache," and

Marion Y. Keith, Greensboro, "Pyuria in Infants and Children." Dr. Thurman D. Kitchin, Wake Forest, spoke on medical history and Dr. Charles F. Strosnider, Goldsboro, president of the state society, made an address.

### NORTH DAKOTA

**Annual Registration Due January 1.**—Every practitioner of medicine and surgery holding a license to practice in North Dakota is required by law to register annually on or before January 1, with the secretary-treasurer of the board of medical examiners, and at that time to pay a fee of \$5 if a resident of North Dakota, or \$2 if a non-resident. A practitioner may not lawfully practice if he has not registered. If he does so his license may be revoked and can be reinstated on the payment of unpaid fees and 50 cents for each month of default.

### OHIO

**Faculty Changes at Ohio State.**—Dr. Charles A. Doan, professor of medicine and medical research, Ohio State University College of Medicine, has been appointed chairman of the department, which has been merged with the medical research department. Among other additions to the faculty are those of Drs. Carl V. Moore as assistant professor of medicine (hematology); George T. Harding III, assistant clinical professor of medicine (psychiatry); Oram C. Woolpert, assistant professor of medicine (infectious diseases); Louis J. Roth, assistant professor of clinical surgery; James K. W. Ferguson and Emil Bozler, Ph.D., assistant professors of physiology, and Lieut. Col. Frank H. Dixon, Medical Corps, U. S. Army, professor of military science.

### PENNSYLVANIA

**Society News.**—Dr. Charles L. Brown, Philadelphia, presented graduate seminars before the Lycoming County Medical Society, Williamsport, December 11, on "Digitalis, Diuretics and Diet in the Management of Cardiac Failure" and "Appraisal of the Therapeutic Measures in the Management of Pneumonia."—Dr. John Huber Wagner, Pittsburgh, addressed the Fayette County Medical Society, Uniontown, December 10, on treatment of fractures.

#### Philadelphia

**Fortieth Anniversary of Pediatric Society.**—The Philadelphia Pediatric Society celebrated its fortieth anniversary at a banquet at the Barclay, December 8. The program included the following speakers: Drs. Herbert B. Wilcox, New York, on "Today's Requirements of the Practicing Pediatrician"; John Lovett Morse, Boston, "The Future of Pediatrics"; Albert Graeme Mitchell, Cincinnati, "Timely Comments on Pediatrics," and Henry H. Perlman, "The Philadelphia Pediatric Society, A Retrospect and Introspect."

**Society News.**—Under the auspices of the Laënnec Society of Philadelphia, Dr. Carl B. Semb, Oslo, Norway, gave an address at the Pennsylvania Hospital, December 4, on "Surgical Treatment of Pulmonary Tuberculosis."—The program of the Metabolic Association of Philadelphia, December 4, was devoted to discussion of the high-carbohydrate, low-fat diet in the treatment of diabetes, with the following speakers: Drs. E. Roland Snader Jr., Edward S. Dillon, Howard W. Schaffer and Joseph T. Beardwood Jr. and Miss Henrietta Pribnow.—Dr. Arthur Bruce Gill delivered the annual oration of the Philadelphia Academy of Surgery, December 7, on "The Surgeon's Hands."

**State Society Honors Dr. Hamill.**—At the annual meeting of the Medical Society of the State of Pennsylvania in Pittsburgh in October, the house of delegates of the society on the recommendation of the board of trustees presented to Dr. Samuel McC. Hamill, Philadelphia, an illuminated manuscript in recognition of his service as chairman of the State Emergency Child Health Committee during the past three years. Dr. Hamill, who is 72 years old, graduated from the University of Pennsylvania School of Medicine in 1888 and has practiced in Philadelphia since 1890. He was professor of diseases of children at the old Philadelphia Polyclinic and College for Graduates in Medicine from 1901 to 1919 and at the University of Pennsylvania Graduate School of Medicine, 1919-1920. He has been president of the American Pediatric Society (1913-1914); the American Child Health Association (1931-1935); the American Academy of Pediatrics (1932) and the American Association for the Study and Prevention of Infant Mortality (1915-1916). He was the first chairman of the section on pediatrics of the Medical Society of the State of Pennsylvania and was chairman of the Section on Diseases of Children of the American Medical Association in 1911. In 1930 he served as chairman of Section I on Medical Service of Presi-

dent Hoover's White House Conference on Child Health and Protection and chairman of the follow-up committee on that section.

### RHODE ISLAND

**Women's Cancer Organization.**—Dr. George T. Pack, New York, was the guest speaker at a meeting in Providence November 16 launching the Rhode Island division of the "Women's Field Army for the Control of Cancer," a national campaign under the auspices of the American Society for the Control of Cancer. The organization will carry on a campaign for early diagnosis and treatment and for public support of the educational work.

**Society News.**—Drs. James P. O'Hare, Boston, and Vincent J. Oddo, Providence, addressed the Providence Medical Association, December 7, on "Interesting Problems in Hypertension and Bright's Disease" and "Transurethral Resection of the Prostate Gland—A Conservative Evaluation" respectively. Drs. William T. Green, Boston, and Franklin P. Lowry, Newton, addressed the association, November 2, on "The Practical Use of Physical Therapy."

### TEXAS

**Society News.**—The Texas Club of Internal Medicine held a meeting at the University of Michigan Medical School, Ann Arbor, October 8-10, with a program of lectures, ward rounds and visits to the laboratories of metabolism and electrocardiography. Dr. Lee Rice, San Antonio, is president of the club.—Drs. George W. McCoy, Washington, D. C., and Royall M. Calder, San Antonio, addressed the Bexar County Medical Society, San Antonio, October 8, on "Etiology, Incidence and Treatment of Undulant Fever" and "Local Experiences in the Diagnosis and Treatment of Undulant Fever" respectively.—Drs. James H. Shane and Sim Driver, Dallas, addressed the Cooke County Medical Society, Gainesville, October 12, on "Care of the Prostatic Patient" and "Fractures of the Neck of the Femur" respectively.—Dr. Henry Grady Bevil, Beaumont, addressed the Jefferson County Medical Society, Beaumont, November 9, on "Use of Liver Treatment in Obscure Deficiency Diseases."—Dr. William L. Parker, Wichita Falls, was elected president of the Texas Association of Obstetricians and Gynecologists at a meeting in Dallas November 1.

### VIRGINIA

**Personal.**—Dr. Leta J. White, Petersburg, was elected chairman of the Women Physicians of the Southern Medical Association at the annual meeting in Baltimore in November.—Dr. Porter P. Vinson, Rochester, Minn., has been appointed professor and head of the department of bronchoscopy, esophagoscopy and gastroscopy at the Medical College of Virginia, Richmond. He will also be in charge of chronic pulmonary diseases at Memorial Hospital.

**University News.**—The third annual graduate course in ophthalmology and otolaryngology was held at the University of Virginia Department of Medicine, October 27-30. Among the guest lecturers were Drs. Harry S. Gradle, Chicago; Bernard Samuels, New York; Gabriel Tucker, Philadelphia, and John R. Richardson, Boston.—Dr. Theodore L. Squier, Milwaukee, addressed the University of Virginia Medical Society, November 16, on "Bone Marrow Insufficiency with Especial Reference to Granulocytopenia."

**Society News.**—Dr. Charles H. Patterson, Lynchburg, addressed the Lynchburg Academy of Medicine, October 5, on pruritus.—At a meeting of the Roanoke Academy of Medicine, October 5, Dr. Littleton Davis, among others, spoke on "Nonsurgical Pyloric Stenosis."—The Dickenson-Buchanan Counties Medical Society was reorganized at a meeting at Haysi, recently, with Drs. Alexander S. Richardson, Grundy, as president, and Tivis C. Sutherland, Haysi, secretary.—At the quarterly meeting of the Southside Virginia Medical Society in Petersburg, December 8, the speakers were Drs. Martillus H. Todd, Norfolk, on "Traumatic Surgery"; Robert Mazet Jr., Norfolk, "Development and Use of Traction in the Treatment of Fractures"; W. Ambrose McGee, Richmond, "Allergy of the Upper Respiratory Tract"; Wright Clarkson, Petersburg, "Uses and Abuses of Radium in Gynecology," and Eugene L. Lowenberg, Norfolk, "Treatment of Varicose Veins by Multiple Ligations and Controlled Injections."

### WASHINGTON

**University News.**—A new \$200,000 infirmary for the health service of the University of Washington, Seattle, has been opened recently, with improved facilities for outpatient service and full hospital equipment for care of inpatients, except surgery.

## GENERAL

**Society for Clinical Research.**—Dr. David P. Barr, St. Louis, was elected president of the Central Society for Clinical Research at its ninth annual meeting in Chicago, November 6-7, and Dr. Lawrence D. Thompson, St. Louis, was reelected secretary. Speakers included:

Drs. J. Arnold Bargen and Lorin D. Whittaker, Rochester, Minn., Studies of the Function of the Small Intestine.  
Dr. Robert A. Kehoe, Cincinnati, The Alimentary Elimination of Normally Ingested Lead.  
Dr. Henry N. Harkins, Chicago, Plasma Hemorrhage.  
Dr. Howard L. Alt, Chicago, Experimental Iron Deficiency.  
Dr. Elmer L. DeGowin, Iowa City, Clinical Study of Serious Complications from Blood Transfusion.

**Another New Journal—"Growth."**—Announcement has been made of the forthcoming publication of a scientific journal to be called *Growth*, for "studies of the basic factors, processes and functions concerned in growth as a fundamental property of nature." It will be published by contributors and subscribers "as a nonprofit cooperative medium for the integration of growth expressions through the basic sciences," according to the announcement. The managing editor is Prof. Norman J. Berrill, D.Sc., department of zoology, McGill University, Montreal. The editorial board is representative of various branches of scientific work. Publication will begin in January 1937 as a series of numbered fasciculi at irregular intervals, one volume a year.

**Congress of Railway Surgeons.**—Dr. William A. McMillan, Charleston, W. Va., was chosen president of the American Association of Railway Surgeons at the annual meeting in Chicago, November 5-7; he succeeded Dr. Don Deal, Springfield, Ill. Vice presidents are Drs. Mathew A. Tinley, Council Bluffs, Iowa; Herman A. Brennecke, Aurora, Ill., and Victor H. Horning, Chicago; Dr. Theodore L. Hansen, Chicago, was reelected treasurer, and Dr. Daniel B. Moss, Chicago, reelected secretary. The next annual meeting will be held at the Palmer House, Chicago, Sept. 20-22, 1937. The speakers included:

Dr. Vernon C. David, Chicago, Obstruction of the Bowel Due to Lesions of the Rectum and Colon.  
Dr. Philip H. Kreuscher, Chicago, The Surgical Treatment of Arthritis.  
Dr. Robert D. Schrock, Omaha, Early Pathology in Bone Tumors.  
Dr. Brennecke, Treatment of Electrocuted Persons.

**Congress of Physical Therapy, X-Ray and Radium.**—The second cruise of the Latin-American Congress of Physical Therapy, X-Ray and Radium will take place March 9-28, to Guatemala City, Guatemala. One boat will sail from Philadelphia March 9 and another from New Orleans March 10. The congress has been arranged for the week of the inauguration of the president of Guatemala and visitors will participate in the festivities at that time. There will be three scientific sessions, Tuesday morning and afternoon, March 16, and Saturday morning, March 20, at the National University School of Medicine, the intervening time to be spent in a trip to the interior of Guatemala. Physicians who wish to attend should apply to Dr. Norman E. Titus, 730 Fifth Avenue, New York, president of the congress, or to Dr. Cassius Lopez de Victoria, 1013 Lexington Avenue, executive director.

**Society for Study of Arthritis.**—The eighth annual meeting of the American Society for the Study of Arthritis was held in New York at the Waldorf-Astoria, December 3-5. The mornings were devoted to round table discussions and the afternoons to presentation of the following papers:

Dr. Benjamin H. Huggins, Evanston, Ill., Nonarthritic Problems in Differential Diagnosis.  
Dr. Raymond L. Jeffery, Seattle, Résumé of Cases Treated with Complement-Fixing Antigens.  
Dr. Carl R. Comstock, Saratoga Springs, Regimen for Arthritis as Employed at Saratoga Springs.  
Dr. Charles Murray Gratz, New York, Fascial Adhesions.  
Dr. Henry Warren Crowe, London, England, Examples of Radiography in the Diagnosis and Control of Treatment of Arthritis.  
Dr. Lazaros G. Hadjopoulos, New York, Direct and Intermediate Pathways for Streptococcal Invasion.

The society held an open meeting at the New York Academy of Medicine Thursday evening, December 3, with the following speakers: Drs. Crowe, on "Differential Sedimentation Test in Arthritis"; Ralph R. Mellon, Pittsburgh, "New Studies in the Dissociation of Hemolytic Streptococci," and Laurence H. Mayers, Chicago, "Drugs for Arthritis: A New One Each Week for Three Thousand Years." Dr. Reginald Burbank, New York, was reelected president; Dr. Hadjopoulos, New York, was elected vice president, and Dr. Charles H. McEnerney, Washington, D. C., reelected secretary.

**Support Requested for Army Medical Library.**—The Medical Library Association at its recent annual meeting adopted a resolution urging Congress to appropriate funds for the maintenance and development of the Army Medical Library. The resolution asked specifically that funds be appropriated for current medical books and periodicals; for the purchase of

back publications lost during years when the appropriation was inadequate; to make the collection and its *Index-Catalogue* as complete as possible, and to defray the cost of printing regularly each year not less than one volume of the *Index-Catalogue*. The association pointed out that the value and completeness of the *Index-Catalogue* depend on the completeness of the files of medical publications in the library and that in recent years the appropriation to the library has been wholly inadequate to provide for acquisition of current publications for use throughout the country and for inclusion in the index.

**Society News.**—At the seventeenth annual meeting of the Association of Surgeons of the Chesapeake and Ohio Railway at White Sulphur Springs, W. Va., November 6-7, speakers included Drs. Walter R. Griess, Cincinnati, on "Treatment of Gastric Ulcer with Special Reference to the Use of Emetine Hydrochloride"; Martillus H. Todd, Norfolk, Va., "Treatment of Pott's Fracture"; Claude C. Coleman, Richmond, Va., "Treatment of Acute Head Injuries with Special Reference to the Cases That Require Operation," and Francis A. Malmstone, Griffith, Ind., "Treatment of Diabetes Mellitus with Protamine Insulin." Dr. Halstead S. Hedges, Charlottesville, Va., was elected president.—Dr. Leroy S. Peters, Albuquerque, N. M., was chosen president-elect of the Southwestern Medical Association at its annual convention in El Paso, November 21. Dr. Chester R. Swackhamer, Superior, Ariz., was installed as president; Drs. Howell S. Randolph, Phoenix, and John W. Cathcart, El Paso, were elected vice presidents and Dr. Orville E. Egbert, El Paso, was elected secretary. The 1937 meeting will be in Phoenix. Dr. William L. Brown, El Paso, was made honorary life president of the association at this meeting.—The Central States Dermatological Association held its annual meeting in Cleveland, December 5. This association is made up of the dermatologic societies of Rochester, Buffalo, Pittsburgh, Cincinnati, Detroit and Cleveland.—The American Association on Mental Deficiency will hold its annual meeting in Atlantic City May 5-8, 1937. Dr. E. Arthur Whitney, Elwyn, Pa., is secretary.—The American Academy of Orthopedic Surgeons will hold its fifth annual convention in Cleveland, January 11-13, at the Hotel Cleveland.

**Arrests Made in the "Eyeswinding Racket."**—The U. S. Post Office Department has made the following arrests in its investigation of the "eyeswinding racket," also known as the "glimmer racket," which has been carried on throughout the country for several years:

Boyce Bateman	Lawrence B. Holtkamp
Harold N. Baxley	Lewis Levy
Samuel Birnstein	William Henry Londergon Jr.
Samuel Bluestine	Frank Mackett Jr.
Iddien Reese Conner	J. C. Murphy
Herbert C. Crangle	Edward Robinson, alias Eddie A.
Lewis Fenburg	William Shapiro
Samuel F. Freedman	Jerry Theeman
John Gray	Elliott George Wilkinson
William E. Hanecy	Mathew O. Wilkinson
Harry Herman Holtkamp	Curtis J. Yeager

All have been charged with violating either federal or state laws in the operation of the racket. THE JOURNAL published a news item concerning Birnstein, November 14, page 1643. Bluestine was sentenced to one year in jail. Gray was sentenced to ten years on the eyeswinding scheme and fifteen years for attempted murder, in the penitentiary at Huntsville, Texas. Murphy received a sentence of five years in the Huntsville prison. Crangle was arrested November 7 and removed to Norfolk, Va., where the indictment is pending. Londergon, said to be a resident of Chicago, was arrested in Carroll, Iowa, November 21, and sentenced at Montezuma, November 30, to serve seven years in the penitentiary at Fort Madison. Robinson also was arrested at Carroll, November 21, and held for removal to Asheville, N. C., where he is wanted on a federal charge in connection with a swindle in that state. In addition to the eyeswinding charge placed against these "fake eye specialists," the government has also accused them of using the mails to defraud. Three indictments have been returned against Mackett and others. The swindlers sent to Mackett the checks which they obtained from their victims and he deposited them in banks for collection, remitting the proceeds, less 10 per cent commission, to the swindlers. Mackett is an attorney in Milwaukee and in addition operates what is known as the Police and Sheriff's Association of America. In the latter operation he sends agents throughout the country to call on police chiefs and sheriffs and induce them to join his association, giving them free accident policies and in return procuring from the chiefs of police and sheriffs letters which are used in the solicitation of advertisements from the banks and business houses. Hanecy, indicted with Mackett in the collection of the checks, is also a lawyer. The postoffice department states that more than 100 men have been engaged in the "glimmer racket."

## FOREIGN

**Society News.**—The Norwegian Medical Association is celebrating its fiftieth anniversary this year. There are now 2,100 physicians in Norway, compared with about 600 in 1885. Dr. Jorgen H. Berner is secretary general of the association and joint editor of its journal.

**Research Council on Rheumatism.**—A British Empire Rheumatism Council was recently organized at a meeting at the Royal Society of Medicine in London with Lord Horder as chairman. The duke of Gloucester accepted an invitation to be president of the council; Dr. William S. C. Copeman was appointed honorary medical secretary and Sir Frank Fox organizing secretary. The object of the council is to organize research throughout the empire into the causes and means of treatment of rheumatism. It was pointed out that in Great Britain this disease is responsible for one sixth of the payments necessary under the national insurance act.

## Government Services

## Government Positions Open

The U. S. Civil Service announces open competitive examinations for three positions: senior medical officer in psychiatry (woman) at St. Elizabeth's Hospital, Washington, D. C., at \$4,600 a year; junior medical officer (intern), \$2,000 a year, and junior medical officer (psychiatric resident), \$2,000 a year. Competitors will not be required to report for examinations at any place but will be rated on their education and experience. Applications must be on file not later than January 7 if from Arizona, California, Colorado, Idaho, Montana, Nevada, New Mexico, Oregon, Utah, Washington or Wyoming and not later than January 4 from all other states. Application forms and information may be obtained from the board of civil service examiners at any first class postoffice, from the U. S. Civil Service Commission, Washington, D. C., or from the U. S. Civil Service district office in Atlanta, Boston, Chicago, Cincinnati, Denver, New Orleans, New York, Philadelphia, Seattle, St. Louis, St. Paul, San Francisco, Honolulu, Balboa Heights, C. Z., or San Juan, Puerto Rico.

## Conference on Venereal Disease Control

A conference on venereal disease control work will be held at the Department of Commerce Auditorium, Washington, D. C., December 28-30. Dr. Thomas Parran, surgeon general, U. S. Public Health Service, will discuss the general purpose of the conference in his address of welcome Monday morning. Other speakers at the general sessions will include:

- Dr. Raymond A. Vonderlehr, assistant surgeon general, division of venereal diseases, U. S. Public Health Service, Recent Extension of Venereal Disease Control Work Through the Provisions of the Social Security Act.
- Dr. Edward S. Godfrey Jr., state health commissioner of New York. The Venereal Disease Control Program in New York State.
- Dr. Earle G. Brown, Topeka, secretary, Kansas State Board of Health, The Venereal Disease Control Program in Kansas.
- Dr. C. Walter Clarke, director, bureau of social hygiene, New York City Department of Health, A Typical Municipal Venereal Disease Control Program.
- Dr. Percy S. Pelouze, assistant professor of urology, University of Pennsylvania School of Medicine, Philadelphia, The Modern Clinical Management of Gonorrhea.
- Dr. John H. Stokes, professor of dermatology and syphilology at Pennsylvania, Clinical Problems in Syphilis Control Today.

## CORRECTION

**Visualization of the Amount of Residual Urine.**—In the article by Dr. Edwin Beer in THE JOURNAL, December 5, page 1886, the reference in the second column to the illustrations should have been to figures 1 to 6. Under figure 4 the legend should read "Excretory cystogram after voiding, showing stone outside the bladder shadow in the ureter meatus." Under figure 5 the legend should read "Excretory cystogram before voiding, showing intrusion of large intravesical prostate." This was introduced to compare with figure 6, in which after voiding there was practically no residual urine, as evidenced in the urogram.

## The Health of London

According to the annual report of the county medical officer of health for London, the infant mortality rate last year was the lowest on record, 58 per thousand live births. There has been a noteworthy reduction in the number of deaths from street accidents, which have fallen from 752 in 1934 to 531 in 1935. Details are given of the migration of population. Until 1881 there was a definite inflow into the "county of London" (the large area, including the suburbs controlled by the London County Council) but since that year the flow has been outward. This is due to the desire, which developed when London became so big, of business men to live in the country and come to town daily for their work. The maximum migration "in" was in the decennium 1841-1851, when it was 251,185. The maximum migration "out" was in 1901-1911, when it was 523,091. During 1921-1931 the migration "out" was 324,261, and in the same period there was an increase of 811,261 in the population of the "outer ring" of London. The figures for the administrative county show the net result of immigration and emigration and disclose that even when the net migration "out" was large there was migration "in" at certain ages, especially of girls between 15 and 20 and of young men between 20 and 25. The maternal mortality for 1935 was 2.58 per thousand live births, the lowest on record. The death rate for tuberculosis was 0.68 per thousand, also the lowest on record.

## The Decline of Population

The decline of population, which has been shown by statisticians to be imminent, is beginning to attract public attention. A population investigation committee has been set up, of which Professor Carr-Saunders (statistician) is the chairman and various societies are represented by well known men—the British College of Obstetrics and Gynecology by Mr. Eardley Holland, the Medical Research Council by Dr. L. S. Penrose, the Royal Economic Society by H. D. Henderson, the British Population Society by Sir Charles Close, F.R.S., the Eugenics Society by Lord Horder and Julian Huxley, the Society of Medical Officers of Health by Dr. Stella Churchill. Other members are Prof. James Young (gynecologist) and Prof. Lancelot Hogben and Dr. R. R. Kuczynski. The two last named are statisticians who have made a special study of population. The program of the committee is not to suggest lines of action but to examine the present situation and the circumstances that have led to it. Since a national problem of the greatest importance has been created by the decline of the birth rate, anxiety about the future will soon be general. It is also likely that there will shortly be inquiries as to what can be done to avert a serious fall in numbers. But it is held that, before useful suggestions can be made, much fuller examination of the position is necessary. About many important aspects of the fall in the birth rate little is known. The committee, which has obtained the services as secretary of Mr. D. V. Glass, a well known writer on population, hopes soon to be able to expand its own organization for research and at the same time arrange for the collection of material, to stimulate investigation by other bodies which engage in research, and to facilitate cooperation and consultation between specialists whose work touches various aspects of the subject.

An organization called the League of National Life is opposed to contraception. It largely represents religious opinion. At a recent meeting Dr. F. J. McCann (gynecologist), who pre-

sided, said that the continued fall in the death rate was concealing the impending decline of population. More children survived and the mean expectancy of life had been raised from fifteen to twenty years since the middle of the last century. The expectancy of life was now 59 years. Already the diminution in the number of young people was being felt in industry. It was computed that in twenty-five years children of 16 would be fewer by a third and that adults from 65 to 74 would be more numerous by a third. The increasing number of old people who had ceased to be producers would impose a burden on the young, who would be still more inclined to shirk the responsibilities of parenthood. As to the causes of the decline, the higher standard of living had brought with it a desire for luxury and amusement which had reacted unfavorably on family life. The attitude of women toward motherhood had changed since they began to claim a larger share in public life. The increase of female employment was another factor. The rapidly spreading use of contraception was exerting its influence more and more in all classes of society. He advocated the closure of the recently established birth control clinics. A resolution was passed "that in the interests of national prosperity and security the government be urged to formulate and carry out a national policy to meet the peril of declining population."

#### The Transport and Storage of Foodstuffs

Much research under government auspices has recently been done on the transport and storage of foodstuffs. The report for 1935 of the food investigation board of the Department of Scientific and Industrial Research, which has just been published, states that in regard to the gas storage of fruit and chilled meat and the brine freezing of fish, general solutions have been found. The right proportion of carbon dioxide to be used in the atmosphere has been ascertained. A good deal of progress has been made in connection with the manufacture of bacon. A survey is being made on the cold storage of herrings. The problem of fruit and vegetables is a different one. The object is to control the living processes during handling and storage, so that after a given time the requirements of the consumer may be satisfied. At present we are far from being able to store raw fruits and vegetables from one season to another, while the qualities after such storage as is common in commerce are in general inferior to the material at its best. The apple, the orange and the banana account for three fourths of the consumption of raw fruit. Fundamental research on the two latter cannot be carried out in this country; it must be done where the fruit is grown. Research is being done in various parts of the empire; on the orange in Australia and South Africa, on the banana in Australia and the West Indies. The storage of tomatoes is being investigated but is hampered by the fact that little is known of the physiology of this fruit.

#### The Use of Analgesics by Midwives

As more than half the labors in this country are attended by midwives, it has been felt that they should have some method of relieving pain. Mr. L. C. Rivett worked out a method of chloroform analgesia by means of 20 minim (1.25 cc.) capsules of chloroform to be crushed and administered to the patient during severe pain. But, as stated in a previous letter (*THE JOURNAL*, March 28, p. 1104) a committee appointed by the British College of Obstetrics and Gynecology to investigate the question whether there is any safe method which can be entrusted to the midwife in the absence of a physician rejected this method. The committee came to the conclusion that nitrous oxide and air might be safely administered by the Minnitt or similar apparatus, provided recent examination by a physician revealed no contraindication. Its use should be restricted to midwives who have been specially trained. The Central Midwives Board, after consultation with the College

of Obstetrics and Gynecology, has drawn up the following rules for such administration: 1. The midwife must have received instruction in obstetric analgesia at an approved institution, which she has satisfied as to her competence. 2. She must have a certificate in writing from a physician who has examined the patient within a month of labor that the latter is in a fit condition for gas and air administration. 3. There must be in the room at the time of administration, in addition to the midwife, one other person who is either a midwife, a state-registered nurse, a senior medical student or a pupil midwife.

For domiciliary administration there is the difficulty of expense. In a letter to the *Times*, Mrs. Baldwin (the wife of the prime minister), who has headed a movement to raise funds to provide analgesia for women who cannot afford to employ a physician, points out that the recent midwives act should greatly assist in the provision of analgesia for all women, rich or poor. Light portable gas and air machines costing from \$42 to \$63 will soon be available. Arrangements for the delivery and collection of gas cylinders for a charge of 84 cents are being made by a well known firm. The average cost of the gas administered in a series of cases was found to be 50 cents. The fact that such analgesia may have drawbacks, which in some cases may outweigh the advantages, is not taken into account.

#### Social Insurance Questions

A correspondent of the *Coucnors médical* (a journal in which considerable space is devoted to queries and answers to social insurance questions) asks, with regard to the legal requirement of a physician's notice of having treated an insured person within three days after the first visit, whether this is required only at the onset of an illness or whether such notice must be sent after every call, and, in cases seen only at intervals of two to three weeks, whether a notice must be sent after each visit.

The answer was that such notification must be made only once and within three days after the first call. As to chronic cases, seen only every few weeks, the question presents as to whether the insured person has already received indemnity for six months. If such is the case, the insured person must arrange to have his invalidity extended for another six months, after having been apparently "cured" for an interval of two months. This last requirement has been the subject of much litigation, but according to recent decisions the patient can have his indemnity prolonged without being obliged to rest without compensation for two months.

A correspondent of the *Coucnors médical* (October 11) states that a female worker who was insured was refused indemnity for medical care to her child because the husband was not insured; hence their children could not benefit by the fact that the mother alone was insured. The answer to this query was that there had been no change in the older law as to result of the passage of the modified law in 1935. The term "insured" is employed irrespective of sex; hence it applies to the wife as well as to the husband. The mother is entitled to recompense for the care of her child even though the father is not insured; hence the claim is a just one and the *caisse*, or disbursing office, of the social insurance organization should be compelled to pay for the child's medical care.

Another correspondent in the October 18 issue asks whether a male worker who receives a pension of 3,900 francs per annum (less than \$200) as the result of invalidity incapacitating him to the extent of two thirds of his working capacity has the right to work a certain number of hours per day or week, corresponding to the remaining third of his former ability to work. The insured has a severe form of diabetes resulting in a two-thirds invalidity. He now works five hours a day instead

of eight as formerly, because the diabetes is in a relatively quiescent stage. The answer to this query was that an insured worker who receives an invalidity pension because of being two-thirds incapacitated has the right to work to the extent (one third) which his health permits. However, the recent law (1935) states that the pension can be suspended whenever the insured has other means equal to the salary received before the invalidity pension was granted. Furthermore, the invalidity pension can be stopped if the ability to work exceeds 50 per cent; hence if the insured person in question does not receive as the result of his two-third incapacity pension and his salary in working a sum equal to that received before being granted the invalidity pension, he can continue to work and receive both his pension and his additional salary.

In the September 27 *Concours médical* a correspondent asks the following question: He wishes to employ a husband and wife as butler and cook respectively. They have an income from property owned by them. Their annual wages at the home of the correspondent of the *Concours médical* are about 10,000 francs. The couple do not wish to join the social insurance, and the question arises whether they have the right to refuse and is the employer liable to a fine, if, as is obligatory in France, he does not pay his share (half) of the monthly premium. The answer to the query was as follows: The revised social insurance law, which went into effect August 21, makes it obligatory for every salaried male or female worker of French nationality who earns 21,000 francs (about \$1,500 before the recent devaluation) to be insured. For workers who have a minimum of one dependent child, this amount is raised to 25,000 francs. If a worker has an income that is independent of the remuneration received for his services, the obligation to be insured is not changed by such additional income. Hence the correspondent was advised not to neglect to notify the social insurance authorities of having employed two persons receiving together a salary of 10,000 francs annually. If the employer fails to do so, the employees can claim from him, in case of sickness, a sum equal to that which should have been paid by both parties by the social insurance fund.

#### A Sidelight on Social Insurance

In the September 20 *Concours médical*, a practitioner asks whether an individual insured under the social insurance law is compelled to submit to an examination by a medical inspector of the caisse, or disbursing office, of the state insurance organization, in the absence of the attending physician. In the reply, the paragraph in the law as modified in October 1935 is cited to the effect that every one insured against illness is obliged to submit to examinations by medical inspectors, a refusal to comply with this requirement resulting in the suspension of all indemnities. Hence the attending physician ought not to advise the insured person to refuse to submit to such an examination, and the insured person cannot insist on the presence of the attending physician. Should the insured person wish to have his physician present, the fee of the latter must be paid by the insured person without any prospect of being recompensed by the insurance caisse, or bureau. The only exception to the necessity of submission to an examination by the medical inspector in the absence of the attending physician is when an inspector interferes with the relation of patient and medical attendant, criticizes the treatment or makes a diagnosis in the presence of the patient which does not conform with that of the attending physician. It is evident that the preceding is one of the weak points of state medicine, because it destroys the confidence between the patient and his physician, which is indispensable to success in treatment. An insured person who is obliged to cease work or travel to a neighboring city for an examination by a medical inspector ought to be recompensed for all expenses, but this question still remains to be decided, according to the *Concours médical*.

#### Fees Received for Social Insurance Cases

If an insured worker wishes to be treated at a hospital that has no contract with the caisses, or disbursing offices, of the social insurance organization, he will be indemnified only at the same rate that is allowed for care at home or in a public hospital. If, however, a private hospital has made a contract to care for the insured, the caisses will pay an agreed sum per diem to the hospital. The amount granted under these circumstances is about equal to that allowed for public hospitals. This per diem allowance is about 42 francs (\$2) and does not include fees for operations, for which such a relatively low allowance is made that, in large cities, vigorous protests have been made to the insurance authorities by the surgical societies.

With regard to fees for the attending staff of public hospitals, by the caisses or disbursing bureaus, the maximum allowed for physicians is 4 francs (20 cents) a day and, for surgeons, fees varying from 6 to 24 francs (\$1.25) will be granted, depending on the type of operation as previously agreed on in accordance with a fee table. July 29 the Syndicat, or Union, of French Surgeons passed resolutions protesting against forcing insured workers to enter public hospitals, because they would be obliged, should they wish to enter a noncontract private hospital, to pay the difference between the per diem charge allowed by the caisses for a contract private or public hospital and the charges of a noncontract hospital. The same was true for surgical fees; hence the Surgical Union demanded that this injustice be corrected by permitting an insured worker to enter a noncontract private hospital and to be indemnified in full for the fees paid to these hospitals and that the surgeons be reimbursed according to an agreed on fee table. Thus the free choice of medical attendant as the French law provides would not be violated and the insured would be considered as such and not as paupers.

#### Social Insurance Law Does Not Permit Choice of Hospital

An important decision was rendered in May by the supreme court to the effect that an insured worker under the social insurance law of 1930 can enter only a private or public hospital that has a contract with the caisses, or local disbursement agencies, of the social insurance organization. If the insured worker chooses a hospital or sanatorium that does not have such a contract, he will receive an indemnity equal only to that which would be granted for a stay in the individual's own domicile. This decision follows considerable litigation during the past two years. The courts of appeal of two departments in 1934 and 1935 and the supreme council of the social insurance organization in August 1935 decided that the insured had the right to choose the institution he wished to enter, whether or not it had a contract with the insurance authorities. An appeal was made from this decision and the supreme court has just overruled the judgment of the lower court, so that, in the future, the free choice of a hospital no longer exists. This decision will work a hardship for many institutions that are unwilling to take care of social insurance cases at the comparatively low rates allowed by the caisses or disbursing agencies.

#### Maud Slye Lectures in Paris

Miss Maud Slye of the University of Chicago, whose research work on the rôle of heredity in cancer has given her an international reputation, lectured on the results of her studies on this subject in the amphitheater of the department of pathology in the medical school (Faculté de médecine) of the University of Paris, October 5.

#### Lecture by Dr. Walter M. Simpson

The value of pyretotherapy in the treatment of syphilis and gonorrhea was the subject of a lecture given by Dr. Walter M. Simpson of Dayton, Ohio, at the Alfred Fournier Institute, June 26.

## BERLIN

## The Treatment of Early Syphilis

In virtually all countries the number of cases of early syphilis has considerably declined during the past fifteen years. But the decline has almost universally not taken place at the rate which might have been anticipated in view of modern procedures for the detection and eradication of syphilis. This fact may perhaps be attributed to the lack of a uniform guiding principle in the application of antisiphilic methods as well as to certain diagnostic difficulties. Not only do fundamental therapeutic principles undergo a constant development from country to country; within one country their perfection depends on the personal experience and method of presentation of the individual clinician. To establish greater international coordination of procedure it should first of all be proved that certain guiding principles of therapy conduce to unmistakably superior results. The Section on Hygiene of the League of Nations with this in mind undertook to assemble material from all the important clinics of Germany, Denmark, France, Great Britain and the United States. This material was then studied and evaluated by Professor Martenstein of Dresden.

Of 25,632 cases thus collected, 15,333 could be designated cases of early syphilis. There is an individual standardized

*Percentage of Cases in Which at Least One Lumbar Puncture Was Done*

Country	Cases of Discontinuous Treatment in Which Lumbar Puncture Was Performed, per Cent	Cases of Continuous Treatment in Which Lumbar Puncture Was Performed, per Cent
Germany .....	28.63	4.13
Denmark .....	5.95	.....
United States .....	56.91	68.40
France .....	8.26	11.11
Great Britain .....	10.28	21.43

record card for each case and in addition each hospital director has appended the answers to a general uniform questionnaire with reference to the therapeutic procedures followed. This material, collected from the best organized and best directed institutions of the respective countries, demonstrated on sifting amazing defects in the practical carrying out of diagnosis and treatment. Consequently a number of fresh syphilis cases, some 13 per cent of the collected cases of fresh syphilis in which the diagnostic and serologic control procedures deviated from recognized methods of the present day, had to be placed in a separate category. In 1,968 cases recorded as seronegative, primary syphilis, positive demonstration of the spirochete was lacking for around 19 per cent despite the fact that such a demonstration constitutes the sole possible proof that the disturbance is of a syphilitic character. In 324 primary cases no attempt to elicit a seroreaction had been made, and in 53 per cent of these cases the spirochete was either not demonstrable or else no attempts had been made to establish its presence. Of a further 3,153 cases recorded as seropositive primary syphilis only 53 per cent were examined for the spirochete, and in only 43.5 per cent of all this number was proof of the presence of the causative agent adduced.

There thus remain to be accounted for only 4,833 cases of primary syphilis and 8,365 cases of secondary syphilis. Even among these cases there was frequent evidence that regular serologic control of any sort was lacking.

Generally speaking, a lumbar puncture was seldom performed. The accompanying table shows the percentage of cases in which at least one lumbar puncture was done. It was further found

that the general fundamental therapeutic principles of particular clinics were adhered to in actual practice in only an infinitesimally small number of the cases treated. Martenstein thought it astonishing that, in spite of this fact, the end results still were forthcoming in relatively favorable measure. He adds that in France the number of cures accomplished in cases of all stages is extremely high; nevertheless, the results obtained in that country through use of discontinuous treatment are not correspondingly favorable. Good end results are to be obtained on the one hand by the so-called continuous treatment, namely, that which is maintained over a long period, and, on the other hand, as in Denmark and Great Britain, by discontinuous (intermittent) treatment. A fair comparison of the benefits of the continuous treatment on the one hand with those of the highly successful discontinuous therapy on the other was not possible on the basis of the material in question.

The committee of the League of Nations then drafted recommendations for the treatment of fresh syphilis. The scheme of the discontinuous therapy is essentially a combination of the English and Danish methods, whereas the guiding principles of the continuous treatment closely follow those which have been established by the Cooperative Clinical Group in the United States.

Martenstein considers as an important point in favor of the continuous treatment that under it the patient is not given the erroneous impression that the treatment has ended, although such an impression is frequently conveyed if discontinuous treatment is used. In the latter a shortening of the intervals between separate treatments would do much to overcome this disadvantage, since a certain regularity in the administration of the treatments would then become more apparent.

## Foundation of the German Society of Hygiene

On the occasion of a meeting of the Society of German Scientific Investigators and Physicians, recently held at Dresden, the German Society of Hygiene was founded. The new society, according to the official announcement, will coordinate all the active forces in the field of hygiene for the more perfect functioning of preventive measures; the society also will seek to assure suitable instruction in hygiene in the universities and the indoctrination of the rising generation in the ideals of comradeship, ethics and honor that relate to hygienic-scientific activity. The society envisages itself as performing another important duty: the discovery of appropriate ways and means by which to indoctrinate Germans of all groups with the concepts of sound, prophylactic attention to health. The direction of the society was entrusted by the National Ministry of the Interior to the president of the National Bureau of Health, Prof. Dr. Hans Reiter. The policies of the society will be shaped by representatives of the ministry, by the national führer of physicians, by numerous research societies and by the social organizations affiliated with the National Socialist party.

The presiding officer of the new society, Professor Reiter, emphasized in this connection that it has been necessary to unite the various trends in hygienic endeavor into one German Society of Hygiene within the framework of which more favorable solution of major problems is assured by the establishment of departments in various special fields. Accordingly in the German Society of Hygiene will be merged the German Association for Public Hygiene, the German Social Hygienic Society and the German Microbiologic Association; further, there will also be indirect representation of the hygienic organizations existing in various localities in Germany, which will be regarded as local units of the German Society of Hygiene. The membership of the society is to include hygienists, both practitioners and scientific investigators, and especially instructors in hygiene in the universities, medical directors of state and communal health departments, medical representatives of the party organi-

zations who serve as hygienists, directors of institutions for care of the sick, and in addition sanitary engineers, sanitary architects, sanitary technicians and sanitary chemists so far as the latter are active in public service (in other words, the membership is not limited to physicians). The German Society of Hygiene will consequently work out a scientific and practical program for the formulation and elucidation of all hygienic problems and in its capacity as adviser to government and party in matters of health render a most welcome assistance to the National Health Bureau.

In conclusion, Professor Heinrich Zeiss of Berlin discussed the national function of German hygiene. It is his belief that the crucial problems of hygiene can be solved only through the new German medicine. The function of German hygiene may best be fulfilled through unified governmental direction as exemplified in the standardization of public sanitary affairs already contemplated. Finical hairsplitting must be abandoned and bacteriology in particular must embrace more synthetic and flexible concepts in theory and practice. The whole task demands a definite organization of German hygienists which must never again be dispensed with. This organized program under party and governmental sponsorship will form the basis for a successful attack on the German national hygienic problems of the future.

#### Injectons by Midwives

According to the terms of a decree just issued by the minister of the interior, the administration of pharmaceutical substances by midwives is to be restricted. The midwife must now abstain from independent administration, either external or internal, of such substances. Exceptions are made in those cases which demand that the patient receive certain medications pending the arrival of a physician as expressly stipulated in the manual of midwifery. According to the new regulations a midwife may administer an injection (a) if instructed to do so by a physician who is present, (b) if instructed to do so by a physician who is not present, (c) in emergency cases if instructed to do so by a physician whose arrival has been delayed. A midwife has no general authority to administer injections.

#### SWITZERLAND

(From Our Regular Correspondent)

Oct. 20, 1936.

#### Iodine Prophylaxis and Endemic Goiter

The canton of Bern is well known as one of those regions in which goiter is endemic. Since 1924 iodized common salt with a content of 5 mg. of potassium iodide to 1 Kg. of sodium chloride has been available to the Swiss public. Since Jan. 1, 1936, this salt has been generally distributed in the canton of Bern and salt that has not been iodized is no longer used. A few years ago the consumption of iodized salt was quite small in the canton of Bern; it amounted in 1933 to only 7 per cent of the total salt consumption, whereas in ten other cantons in late years nearly 100 per cent of the salt purchased was iodized and in another five cantons the corresponding figures stood between 50 and 100 per cent. Since many laymen and physicians have asserted that even a minimal admixture of iodine in common salt may be injurious, all alleged harmful effects of the iodine have to be carefully examined. The effectiveness of iodized common salt in the prophylaxis of goiter must, on the other hand, be studied. Dr. Wegelin, the Bern professor of pathologic anatomy, called attention in 1926 to the fact that the histologic picture of the thyroid in a new-born infant assumed a normal appearance if the mother had ingested iodized common salt during pregnancy. Large vesicles containing colloid were seen to appear in such cases. Wegelin was able, subsequently, to verify his observations many times. The weight of the thyroid of the new-born also underwent remarkable reduction: in seventeen of eighteen cases in which the gravid

mother had used iodized common salt, iodine tablets or other preparations containing iodine the weight was from 1 to 6 Gm. In the remaining case it was 14 Gm. Unfavorable results also have been reported from some of the cantons, but others have reported notable successes. For example, in the Ausser-Rhodèn section of the canton of Appenzell, more strongly iodized salt with 10 mg. of potassium iodide to 1 Kg. of salt has been in use since 1922. Congenital struma is on the way to complete disappearance in that locality. Animal experiments of Schmeling have demonstrated, moreover, that the thyroids of newly born rats are richer in colloid if the mother has been supplied iodine in small amounts.

As only scanty data on the iodine need of pregnant mothers were available, Wegelin induced his assistant, Dr. Steinmann, to make larger scale tests of the influence of iodine prophylaxis on the thyroid of the new-born. Steinmann collected data from the years 1909 to 1934 on the absolute and relative weight of the thyroid of 178 newly born infants. The material was divided into five groups on the basis of five year periods, save that the first group represented six years in order to include a sufficient number of cases. The two periods following 1924, that is, after the beginning of iodine prophylaxis with iodized common salt and other substances containing iodine, were now compared with the three previous periods and an unmistakable decrease in the absolute and relative weight of the thyroid was noted for the more recent years. For the period 1930-1934 the difference of the mean value exceeded the threefold mean error all along in contrast to the period prior to 1924, so that according to statistical rules the difference possesses a sure factual importance, whereas this cannot be universally established for the years 1925-1929. Furthermore, in the last decade an increase in the number of thyroid bodies of lesser weight (below 3 or, say, 6 Gm.) could be determined, whereas the number of large struma cases remains unchanged, as was to be expected. Among the prematurely born also the relative thyroid weight has sunk plainly since 1924. As there has apparently been no migration of pregnant women from goiter-free regions, it must be assumed that the decrease in weight of the thyroid among the new-born depends principally on the iodine prophylaxis of goiter.

By a second series of examinations, Schnetz has now determined that since 1924 a change in the character of the thyroid of children and of young adults has also appeared. A total of 8,460 cases covering the years 1909-1934 was collected, arranged according to age and, like the other group, divided into five periods of five or six years each. The data evidenced an obvious increase in the weight of the normal thyroid during the years 1930-1934 in persons from 5 to 25 years of age; that is, precisely in those persons whose thyroids were still in a sensitive state (the stage of diffused hyperplasia) at the time of the introduction of iodine prophylaxis. Hence, in this age group, a considerable decrease in cases of struma nodosa has occurred. The difference in the values in the years 1930-1934 here too has considerably exceeded the threefold mean error as opposed to the value in the period prior to 1924. In the upper age group (over 30), as had been expected, the number of nodular goiters remained approximately stationary, since the iodine no longer causes the nodes to disappear and, according to earlier examinations, from the twentieth year forward the incidence of struma nodosa in Bern amounts to between 67 and 90 per cent. Diffused struma tended to decrease among the youthful age groups from 1930 to 1934.

From these statistics it must be concluded that endemic goiter is on the wane in the canton of Bern and that iodine prophylaxis is largely responsible for this subsidence. To be sure, the influence of possible migrations from goiter-free regions has yet to be carefully examined. A more authentic perspective of the effect of iodized common salt will first be possible thirty years hence, after a greater number of the Bernese population

developed from fetal life to adulthood under the influence of iodine prophylaxis. In that time it will likewise be seen whether the iodine dosage should perhaps be increased and whether any cases appear refractive to iodotherapy; that is, cases in which persons develop goiter in spite of the administration of iodine. The results to date still permit of the conclusion that with iodine prophylaxis the beginnings of a successful fight on goiter have been made.

Of further interest are the clinical data furnished as supplementary to the foregoing report and also discussed in the Bern Medical Society, all the more so as on the question of goiter prophylaxis by iodized common salt there still exists no unity of opinion even in the canton of Bern, wherein the disease may be so adequately observed. Professor Burgi, pharmacologist, stated in this connection that it was virtually impossible to form a durable basic compound of common salt and potassium iodide; it should be assumed therefore that occasionally a greater amount of iodine will be ingested. The amount, nevertheless, is still so small that reports of its injuriousness can scarcely be credited.

Prof. H. Guggisberg, gynecologist, verified Professor Wegelin's finding that to achieve maximal effect prophylaxis of goiter must be introduced before birth. Physical studies at the Woman's Clinic have disclosed that a large majority of infants are born with manifestly enlarged goiter. The measurements were taken on the third or fourth day when swellings due to birth had already completely disappeared and nevertheless the thyroid nearly always exhibits an essential hypertrophy, particularly pronounced in the lateral lobes. Not only is congenital struma a bodily defect for the new-born: it may bring its train extensive cardiac alterations in the form of enlargement, besides disturbances of the longitudinal growth and of ossification. Therefore the inauguration of iodine treatment for pregnant women encountered difficulties in many communities, as a number of investigators are of the opinion that there is a hyperthyreosis coextensive with pregnancy. The latter advise against the administration of iodine in pregnancy. Conversely, extensive investigations at the Guggisberg clinic have demonstrated that no certain signs of hyperthyreosis are evidenced.

Professor Glanzmann, pediatrician, stated that struma neonati are extraordinarily sensitive to iodine. A single dosage of 1 mg. of potassium iodide suffices to bring the gland to normal size. Now and then goiter is present in nurslings who have received an unvaried milk diet. The iodine tolerance of goitrous nurslings and children is in general excellent. In the common salt iodine prophylaxis and that administered in schools, Glanzmann hardly observed any hypersensitivity. On the other hand, some cases of large parenchymatous struma were observed among children, and this type of disease almost always showed itself refractive to iodotherapy.

Yet when all is considered on the basis of the collected data, the constant recession of goiter since 1924 speaks plainly for the effectiveness of iodine prophylaxis.

In this connection, several recent studies of endemic cretinism should be mentioned. This disease and endemic goiter are usually encountered in the same geographic regions. The investigations of this difficult problem, as it exists in Switzerland, by the Medical Faculty of Bern, have been most fruitful. The Bernese surgeon Theodor Kocher, a pioneer in his time, determined the similarity of manifestations in cretinism and in subjects who had undergone total extirpation of the thyroid. The theory that cretinism may be explained as a pure hypothyreosis (hypofunction of the thyroid) fails to receive full support either from observations among human beings or by experimentation with animals. A complete solution of this problem is not as yet possible. A forthcoming book entitled "Endemic Cretinism" by Professor de Quervain, now a surgeon at Bern, and Professor Wegelin contains the following statement based on exten-

sive investigation of the field: "We know with certainty that endemic cretinism is attributable to a dysfunction of the thyroid produced by goiter noxa and that this dysfunction, already present in fetal life, continues in extra-uterine life to damage the thyroid body at a varying rate and in varying degree. Directly parallel, harmful effects on the entire organism by the noxa of goiter and simultaneous involvement of the other endocrines are possible but have not yet been demonstrated by anatomic, clinical or experimental evidence. For the peripheral disturbance of the organs of hearing there is still lacking up to the present an authoritative explanation of any kind whatever. The same is true of the increased incidence of cardiac disturbances, hernia, adenoid vegetations and an even apparent incidence of actual deformity within the endemic zones. It must be added that in future a complete solution of the problem will be reached only if, instead of singling out the goiter-free cretin dwarfs as was formerly done, all aspects of endemic thyreopathy are considered within the scope of investigations."

In the chapter on the prophylaxis and treatment of cretinism, Professor de Quervain guardedly refrains from use of the term "race hygiene" sometimes employed in this connection. Cretinism bears no relation to any race. Cretin offspring may appear among all races of men wherever the parental environment predisposes to the so-called noxa of goiter. Faulty, unhygienic living conditions are an important factor in the goiter zones. The most important factors in prophylaxis are housing in the widest sense of the term and the consideration of ventilation, light, good drinking water and good food. According to experimental demonstration, small doses of iodine act as a check on the noxa of goiter.

Cretinism cannot be considered a heritable disease in the true sense, as the majority of cretins are not the offspring of cretin parents but of normal parents, although to be sure the mother is frequently goitrous. Any sterilization legislation is in this connection out of place. As de Quervain emphasizes: "To sterilize all goitrous women because they may give birth to cretins would be to exterminate one section of the population for the benefit of another section which would in turn be subject to the same fate." Persons who present cretinism in its milder forms may become altogether useful citizens. Cretins possess such pleasant characteristics as "unfailing optimism," wittiness, liveliness, at repartee, gratitude and a sense of humility. "Regions in which cretinism forms the undertone are therefore unsuitable for revolutionary experiments."

The theoretical concept of cretinism as a hypothyreosis has suggested that substitution therapy be attempted. However, the end results alike from implantation of a thyroid tissue that is capable of function as from the medicinal administration of thyroid preparations were, according to Professor de Quervain, "altogether modest."

### Neurosurgery of Kidney

Dr. Silva de Assis, of Bello Horizonte, recently published an article on neurosurgery of the kidney, in which he reaches the following conclusions: The innervation of the kidney originates only in the autonomic nervous system. The reflex phenomena of sensory and secretory nature that take place in pathologic conditions of the urinary tract originate in interconnections of the ganglions of the renal plexus and in anastomoses of renal nerves. Fibers of smooth muscle are abundant in the structure of the calices, renal pelvis and ureter, as proved by histo-anatomic and physiologic studies of the structures. Peristalsis in the structures results from tonicity and contractility of smooth muscle fibers. The normal passage of urine from the kidney to the bladder is not passive. Peristaltic waves originate at the renal pelvis and propagate through the ureter, the seg-

ments of which are stimulated to progressive dilatation and contraction by the passage of urine. In these conditions there are simultaneously ureteral segments filled with urine and empty segments of the ureter. Renal nerves are not indispensable for the functions of the organ. The anatomic section of the renal nerves results in development of renal hypertrophy. The total functional capacity of enervated kidneys is increased in comparison with that of normal kidneys. Section of the renal nerves does not prevent peristalsis for the conduction of urine, which is maintained by the fibers of smooth muscle in the structures. Spasm of the smooth muscles of the urinary tract in pathologic conditions may result in obstructing the tract at the level of the calices, renal pelvis or ureter, with consequent retention of urine in the segment immediately over the obstructed one. Retention of urine is a frequent urologic disease in which stasis at the renal pelvis is the most frequent symptom. Satisfactory results in treating the condition depend on making an early diagnosis. The presence of a neuromuscular disequilibrium of renal sympathetic origin is the most important pathogenic factor of urinary retention and the cause of spasms, pain and muscular hypertonia. Total enervation of the kidney is indicated in retention of urine. It results in the control of pain and in reestablishing urination without causing disturbances to normal renal functions. The technic of the operation is described.

#### Tonic Pupil (Adie's Syndrome)

Prof. E. Vampré, in a recent lecture before the Associação Paulista, made a study of tonic pupil. The nature and seat of the disease are unknown. The condition was described in the literature in 1931. Subirana of Barcelona wrote a monograph on the subject in 1935. The most important point of Adie's syndrome is the one concerning the differential diagnosis from myotonic pupil and also from Argyll Robertson's sign. In the latter sign, frequently both pupils are involved in the miotic condition and the pupils are slightly dilated under the effect of cocaine and atropine. Pupillary myotony ordinarily is unilateral and the diameter of the pupil is rarely less than 3 mm. The pupil is normally dilated under the effect of cocaine and atropine. It contracts to convergence only after a few seconds and the contraction may increase even after suspension of convergence and accommodation. The pupil returns slowly to its original diameter.

### Marriages

DONALD STRATTON SEARLE, Worcester, Mass., to Miss Ruth Westcott Sheppard of Germantown, Pa., October 24.

GEORGE R. BARRETT, Pioneer Mine, B. C., Canada, to Miss Marjorie Elaine Gibbons of Nanaimo, in August.

MERCHISLAW M. SARNECKI, St. Paul, to Miss Margaret Fahnestock of Lincoln, Neb., September 6.

JEROULD A. CAMPBELL, Lockport, N. Y., to Miss Mary Dolores Griffin of Hornell, October 3.

HORACE ASA DAY, Orlando, Fla., to Miss Mary Elizabeth Schlater of Toledo, Ohio, October 10.

WILLIAM THOMAS CLARY to Mrs. Polly Gordon Bledsoe, both of Greensboro, N. C., in October.

WILLIAM E. LOCKHART JR., Canyon, Texas, to Lora Bell Kunze of Minneapolis, August 24.

JAMES FLEXNER, New York, to Miss Dorothy Mac Ensheimer of Harrison, N. Y., November 26.

DEWEY THURMAN NABORS to Miss Ida Susannah Thomas, both of Atlanta, Ga., October 10.

FRANK VANN CHAPPELL, Marianna, Fla., to Miss Mary Lee Lindsey of Perry, September 12.

JAMES M. CAMPBELL to Miss Lucile Box, both of Newton, Miss., September 12.

PAUL J. BLESSINGER to Miss Jo Gerber, both of Jasper, Ind., October 27.

### Deaths

William Lafayette Rich ☉ Salt Lake City; Washington University School of Medicine, St. Louis, 1907; member of the House of Delegates of the American Medical Association in 1923; past president and secretary of the Utah State Medical Association; fellow of the American College of Physicians; member of the medical advisory board during the World War; on the staffs of the Latter-Day Saints Hospital, Salt Lake General Hospital, Children's Hospital and St. Mark's Hospital; aged 58; died, November 17, of chronic myocarditis.

William Hobbs Pritchard ☉ Columbus, Ohio; Miami Medical College, Cincinnati, 1900; member of the American Psychiatric Association; for many years instructor in medicine in the mental department, Ohio State University College of Medicine; served during the World War; physician to the Ohio Hospital for Epileptics, Gallipolis, 1903-1905, and superintendent, 1905-1911; physician to the Columbus State Hospital, 1901-1903, and since 1916 superintendent; aged 69; died, November 11, of myocarditis.

Joseph Hume ☉ New Orleans; Medical College of the State of South Carolina, Charleston, 1901; professor of urology, emeritus, Tulane University of Louisiana School of Medicine; member of the American Association of Genito-Urinary Surgeons and the Clinical Society of Genito-Urinary Surgeons; fellow of the American College of Surgeons; on the staffs of the Touro Infirmary and the Flint Goodridge Hospital; aged 60; died, October 17, of glomerular nephritis.

Stanley Perkins Warren, Portland, Maine; Yale University School of Medicine, New Haven, Conn., 1874; member and past president of the Maine Medical Association; member of the New England Obstetrical and Gynecological Society; had served as obstetrician on the staffs of the Maine General Hospital, Maine Eye and Ear Infirmary and Webber Hospital; author of "Principles of Obstetrics"; aged 90; died, October 5, of hypertensive heart disease.

Charles Duncan ☉ Concord, N. H.; Harvard University Medical School, Boston, 1903; secretary of the New Hampshire Board of Registration in Medicine and State Board of Health; for many years member of the city board of education; on the staffs of the State Hospital, the Margaret Pillsbury Hospital and the New Hampshire Memorial Hospital; aged 64; died, November 12, of carcinoma of the stomach.

George Chenery Anthony ☉ Wellesley, Mass.; Boston University School of Medicine, 1904; member of the New England Roentgen Ray Society; served during the World War; member of the staffs of the Newton (Mass.) Hospital, Waltham (Mass.) Hospital, Leonard Morse Hospital, Natick, and the Union Hospital, Framingham; aged 57; died, October 22, of hypertensive heart disease and pneumonia.

Robert Grant Thayer ☉ Indianapolis; Indiana University School of Medicine, Indianapolis, 1930; on the staffs of the Methodist Hospital, City Hospital and Indiana University Hospitals; formerly on the staffs of the Central State Hospital, Indianapolis, and the State Hospital, Richmond; aged 34; died suddenly, October 30, in Richmond, of acute cardiac dilatation.

Lester Howard McAllister, Port Jervis, N. Y.; University and Bellevue Hospital Medical College, New York, 1908; member of the Medical Society of the State of New York; served during the World War; formerly member of the board of education; on the staff of St. Francis Hospital; aged 51; died, October 17, of myocarditis and coronary occlusion.

Fred Albro Pringle ☉ Montclair, N. J.; Maryland Medical College, Baltimore, 1912; member of the staff and formerly medical superintendent of the Essex County Hospital for Contagious Diseases, Belleville; member of the staff and secretary of the medical board of the Mountinside Hospital; aged 48; died, October 11, of coronary thrombosis.

Randolph Lucien McCalla, Boise, Idaho; Columbia University College of Physicians and Surgeons, New York, 1920; at one time assistant in medicine, instructor in medicine and assistant clinical professor of medicine at the University of California Medical School, San Francisco; aged 40; died, October 10, of uremia and cerebral edema.

Frederic Codman Cobb, Gloucester, Mass.; Harvard University Medical School, Boston, 1887; member of the Massachusetts Medical Society and the American Laryngological, Rhinological and Otological Society; aged 76; died, October 11, in the Baker Memorial Hospital, Boston, of gastric ulcer with massive hemorrhage and coronary sclerosis.

Thomas George Sloan @ Manchester, Conn.; Columbia University College of Physicians and Surgeons, New York, 1899; formerly instructor in anesthetics at Yale University School of Medicine, New Haven; for many years on the staff of the Manchester Memorial Hospital; aged 61; died suddenly, October 30, of coronary occlusion.

Clinton M. Hiestand, Springfield, Ohio; Medical College of Ohio, Cincinnati, 1894; member of the Ohio State Medical Association; past president of the Clark County Medical Society; served during the World War; at one time city physician; formerly on the staff of the City Hospital; aged 69; died, October 12, of uremia.

Fremont W. Scott, Medina, N. Y.; Hahnemann Medical College of Philadelphia, 1880; past president and secretary of the Orleans County Medical Society; formerly physician to the board of health of Medina and coroner; aged 80; on the staff of the Medina Memorial Hospital, where he died, October 19, of coronary occlusion.

Alexander Hofheimer @ New York; Columbia University College of Physicians and Surgeons, New York, 1909; professor of internal medicine at the New York Polyclinic Medical School and Hospital; on the staffs of the Polyclinic and Gouverneur hospitals; aged 50; died, October 27, of coronary thrombosis.

Benjamin H. Beydler, Bridgewater, Va.; Baltimore University School of Medicine, 1897; member of the Medical Society of Virginia; on the staff of the Rockingham Memorial Hospital, Harrisonburg; aged 64; died, October 27, as the result of injuries received in an automobile accident last June.

Robert Borneman Ludy, Atlantic City, N. J.; Medico-Chirurgical College of Philadelphia, 1898; Hahnemann Medical College and Hospital of Philadelphia, 1900; formerly associate in medicine, Temple University School of Medicine, Philadelphia; aged 66; died, October 2, of cerebral hemorrhage.

August Severin Eggers, Grand Forks, N. D.; Kongelige Frederiks Universitet Medisinske Fakultet, Oslo, Norway, 1889; member and past president of the North Dakota State Medical Association; fellow of the American College of Surgeons; aged 73; died, October 7, of pernicious anemia.

Edward B. Gossett @ Kansas City, Mo.; University Medical College of Kansas City, 1894; for many years surgeon in charge of the Atchison, Topeka and Santa Fe Railway Hospital, Ottawa, Kan.; aged 71; died, October 16, in St. Joseph Hospital, of pulmonary embolism and bacillary dysentery.

Alvah A. Swayze, Hackensack, N. J.; College of Physicians and Surgeons, Baltimore, 1897; member of the Medical Society of New Jersey; past president of the Bergen County Medical Society; for many years on the staff of the Hackensack Hospital; aged 67; died, October 17, of paralysis agitans.

John Fleming Chamberlain, Natchez, Miss.; Tulane University of Louisiana Medical Department, New Orleans, 1906; member of the Mississippi State Medical Association; one of the owners of the Chamberlain-Rice Hospital; aged 59; died suddenly, October 26, of coronary thrombosis.

Eugene Joseph Callahan @ Staten Island, N. Y.; University of the City of New York Medical Department, 1894; past president of the Richmond County Medical Society; a founder and on the staff of St. Vincent's Hospital; aged 65; died suddenly in October.

Matthew Barr Grieve, Spokane, Wash.; University of Oregon Medical School, Portland, 1897; member of the Washington State Medical Association; at one time county coroner and city health officer; aged 71; died, October 6, of diabetes mellitus and uremia.

George Webster, Southbridge, Mass.; Baltimore Medical College, 1900; member of the Massachusetts Medical Society; formerly member of the board of health of Southbridge and school physician; on the staff of the Harrington Memorial Hospital; aged 61; died, October 27.

Charles Blim, Crete, Ill.; Rush Medical College, Chicago, 1888; member of the Illinois State Medical Society; formerly secretary of the southern Cook County branch of the Chicago Medical Society; for many years a member of the school board; aged 77; died, October 9.

Ralph Sherrick Chamberlain, Denver; Western Pennsylvania Medical College, Pittsburgh, 1903; at one time chief demonstrator of anatomy, Denver College of Physicians and Surgeons; aged 57; died, October 13, in the Presbyterian Hospital of heart disease.

Frank Hamilton Hunt @ Boston; University of Virginia Department of Medicine, Charlottesville, 1899; associate in

medicine at Harvard University Medical School; on the staff of the Sanatorium Division of the Boston City Hospital; aged 60; died, October 26.

William Patrick John Burke, Hamden, Conn.; Yale University School of Medicine, New Haven, 1890; served during the World War; aged 68; died, October 17, in the Veterans Administration Facility, Newington, of heart disease and pulmonary tuberculosis.

David Miller Shoemaker @ Waynesboro, Pa.; Pulte Medical College, Cincinnati, 1905; served during the World War; past president of the Franklin County Medical Society; aged 63; on the staff of the Waynesboro Hospital, where he died, October 9, of carcinoma.

John Miller Beggs, Chattahoochee, Fla.; Atlanta (Ga.) Medical College, 1914; member of the Florida Medical Association; aged 47; for many years on the staff of the Florida State Hospital, where he died, October 28, of carcinoma of the esophagus.

Frederick William Hander, Beaumont, Texas; University of Nashville (Tenn.) Medical Department, 1900; also a drug-gist; veteran of the Spanish-American War; aged 63; died, October 14, in the Veterans Administration Facility, Los Angeles.

Edgar Clide Webb @ Canon City, Colo.; Indiana University School of Medicine, Indianapolis, 1913; past president of the Fremont County Medical Society; on the staff of the Colorado Hospital; aged 53; died, October 30, of pneumonia.

Francis Kennedy Armstrong, Fort Myers, Fla.; M.B., University of Toronto Faculty of Medicine, 1892; and M.D., Victoria University Medical Department, Coburg, Ont., 1892; aged 68; died, October 26, in the Lee Memorial Hospital.

Richard J. Ellis, New York; Queen's University Faculty of Medicine, Kingston, Ont., Canada, 1910; aged 57; died, September 28, of self-inflicted incised wounds and of injuries received when he jumped from an eight story window.

William Bradford Blanchard @ Framingham, Mass.; University of Maryland School of Medicine, Baltimore, 1914; aged 56; died, October 13, in Palmer Memorial Hospital, Boston, of cerebral thrombosis and diabetes mellitus.

Lloyd R. Atkins, New York; Hahnemann Medical College and Hospital, Chicago, 1887; served during the World War; on the staff of the New York Medical College and Flower Hospital; aged 69; died, October 7, of heart disease.

Louis David Hughes @ Minneapolis; St. Louis University School of Medicine, 1909; served during the World War; member of the staff of the Deaconess Hospital; aged 48; died suddenly, October 23, of coronary thrombosis.

William Egbert, Calgary, Alta., Canada; M.B., University of Toronto Faculty of Medicine, 1889; M.D., Victoria University Medical Department, Coburg, Ont., 1889; formerly lieutenant governor; aged 79; died, October 15.

Simon M. Chess, Brooklyn; Long Island College Hospital, Brooklyn, 1912; member of the Medical Society of the State of New York; formerly assistant in medicine at his alma mater; aged 58; died, October 14, of heart disease.

Wallace Archibald Watson, Ponce Coupe, B. C., Canada; Northwestern University Medical School, Chicago, 1908; formerly on the staff of the Ponce Coupe Hospital; aged 52; died suddenly, October 14, at Dawson Creek.

John William Lucas, Brookville, Ind.; Indiana Medical College, School of Medicine of Purdue University, Indianapolis, 1907; member of the Indiana State Medical Association; aged 55; died, October 1, of angina pectoris.

Harvey S. Kelsey, Willis, Mich.; Saginaw (Mich.) Valley Medical College, 1901; American Medical Missionary College, Chicago, 1905; aged 65; died, September 4, in the University Hospital, Ann Arbor, of meningitis.

Ellis Schwied, Chicago; Chicago College of Medicine and Surgery, 1914; on the staffs of the Mount Sinai Hospital and the Frances E. Willard Hospital; aged 46; died, November 27, of coronary thrombosis.

Lenzy E. McClure, Walnut Grove, Mo.; St. Louis College of Physicians and Surgeons, 1903; member of the school board; aged 64; died, October 11, in a hospital at Springfield, of cerebral hemorrhage.

Bert H. Honeywell @ Ann Arbor, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1909; also a dentist; aged 59; died suddenly, October 4, of coronary thrombosis.

**William F. Beverly**, Nicholasville, Ky.; Medical College of Ohio, Cincinnati, 1888; aged 77; died, October 2, in the Good Samaritan Hospital, Lexington, of acute colitis and pulmonary emphysema.

**Charles Alexander Houston** \* Park Rapids, Minn.; University of Minnesota College of Medicine and Surgery, Minneapolis, 1901; aged 60; died, October 30, of coronary occlusion and arteriosclerosis.

**Frank Lee Cato**, Leslie, Ga.; Jefferson Medical College of Philadelphia, 1887; member of the Medical Association of Georgia; aged 73; died, October 23, of chronic nephritis and diabetes mellitus.

**Lee Wilbert Roiler**, Richmond, Ind.; Kansas Medical College, Medical Department of Washburn College, Topeka, 1905; served during the World War; aged 62; died, October 15, of diabetes mellitus.

**Frank Conquellon Titzell**, Iowa City, Iowa; Chicago Homeopathic Medical College, 1889; member of the Iowa State Medical Society; aged 73; died, October 18, of carcinoma of the stomach.

**Stanley James Keyes**, New York; Long Island College Hospital, Brooklyn, 1908; member of the Medical Society of the State of New York; aged 53; died, October 4, of coronary thrombosis.

**Theodore Miller Leonard**, Buffalo; University of Buffalo School of Medicine, 1901; formerly assistant professor of medicine at his alma mater; aged 59; died, November 19, of bronchopneumonia.

**John Crockett Newton**, San Francisco; University of California Medical Department, San Francisco, 1902; aged 61; died, September 15, of arteriosclerosis, hypertension and bronchopneumonia.

**Joel Hasty Massie**, Dallas, Texas; College of Medicine and Surgery, Chicago, 1909; aged 48; died, September 18, in the Good Samaritan Hospital, Los Angeles, of auricular fibrillation.

**Robert W. Hawkins**, Brazil, Ind.; Medical College of Indiana, Indianapolis, 1895; served during the Spanish-American and World wars; aged 64; died, October 25, of cirrhosis of the liver.

**Nicholas Argyr**, Del Norte, Colo.; University of Colorado School of Medicine, Denver, 1934; member of the Colorado State Medical Society; aged 33; died, October 3, of pneumonia.

**Andrew Olans Flom**, Chisago City, Minn.; University of Minnesota College of Medicine and Surgery, Minneapolis, 1912; aged 50; died suddenly, October 28, of cerebral hemorrhage.

**Harold Peter Prewett**, Antioch, Calif.; University of California Medical School, San Francisco, 1930; aged 32; was killed, September 5, near Reading, in an automobile accident.

**Alice Hall Chapman**, San Francisco; Woman's Medical College of Pennsylvania, Philadelphia, 1886; aged 78; died, September 10, in the Stanford Hospital, of myocarditis.

**Charles Ballard Hall**, Copenhagen, N. Y.; New York Homeopathic Medical College and Hospital, 1894; aged 68; died, October 18, of renal calculi and diabetes mellitus.

**Henry B. Thompson**, Hillsboro, Ohio; Medical College of Ohio, Cincinnati, 1882; aged 84; died, September 16, in the Hillsboro Hospital, of a hip fracture received in a fall.

**Rowland Peter Wild**, Traer, Iowa; State University of Iowa College of Homeopathic Medicine, Iowa City, 1903; aged 56; was killed, October 24, in an automobile accident.

**Edwin Norman Chaney**, Pasadena, Calif.; Hahnemann Medical College and Hospital, Chicago, 1891; aged 71; died, October 11, of nonalcoholic cirrhosis of the liver.

**Henry Mark Koles** \* New York; Bellevue Hospital Medical College, New York, 1892; aged 75; died, October 15, in the Mount Sinai Hospital, of acute appendicitis.

**James Augustus Trotman**, Philadelphia; Temple University School of Medicine, Philadelphia, 1908; aged 60; died suddenly, October 29, of chronic endocarditis.

**John G. Maeder**, New York; New York Homeopathic Medical College, 1885; aged 81; died, October 12, in Upper Nyack, N. Y., of hypertensive heart disease.

**William Patrick Cross** \* Boston; Harvard University Medical School, Boston, 1896; aged 63; died, October 21, of coronary thrombosis and chronic myocarditis.

**Robert Hislop**, Detroit; Faculty of Medicine of Trinity College, Toronto, Ont., Canada, 1883; aged 80; died, October 4, in the Henry Ford Hospital of pneumonia.

**Porter W. Stevenson**, Gettysburg, Pa.; College of Physicians and Surgeons of Chicago, 1884; aged 89; died, September 3, of heart disease and arteriosclerosis.

**Solomon Baumgarten** \* Milwaukee; Medizinische Fakultät der Universität Wien, Austria, 1922; aged 39; died, October 11, in St. Joseph's Hospital of endocarditis.

**Royal August Henry**, Salinas, P. R.; Hahnemann Medical College and Hospital of Philadelphia, 1909; aged 49; died recently of staphylococcal septicemia.

**Ernest Frank Ruppe** \* New York; Bellevue Hospital Medical College, New York, 1883; aged 71; died, October 26, of chronic nephritis and myocarditis.

**William B. Radford**, Hopkinsville, Ky.; University of Louisville Medical Department, 1883; aged 75; died, September 17, of organic heart disease.

**Vance Gist**, Frederick, Okla.; Vanderbilt University School of Medicine, Nashville, Tenn., 1880; aged 82; died, September 22, of cerebral hemorrhage.

**William Joshua Webb**, Los Angeles; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1878; aged 86; died, September 13.

**Theodore W. A. Blank**, St. Louis; Beaumont Hospital Medical College, St. Louis, 1890; aged 73; died suddenly, October 6, of heart disease.

**George Hathaway Gleason**, Milton, Mass.; Harvard University Medical School, Boston, 1902; aged 58; died, October 7, of cirrhosis of the liver.

**Forenci Elixir Hill**, Bainbridge, N. Y.; Eclectic Medical College of the City of New York, 1893; aged 72; died, October 21, of heart disease.

**Peyton L. Campbell**, Dallas, Texas; University of Louisville (Ky.) Medical Department, 1894; aged 70; died, October 1, of chronic nephritis.

**Charles H. Day**, Dayton, Wash.; Hahnemann Medical College and Hospital, Chicago, 1886; aged 80; died, October 5, of chronic myocarditis.

**Alonzo J. Marlar**, Billingsley, Ala.; Memphis (Tenn.) Hospital Medical College, 1892; aged 85; died, October 10, of mitral insufficiency.

**Houston Mifflin**, Norwood, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1879; aged 85; died, September 22.

**Emmet William Barry** \* Whitinsville, Mass.; College of Physicians and Surgeons, Baltimore, 1897; aged 65; died, October 6, of pneumonia.

**Philip B. Amunson**, Mondovi, Wis.; Rush Medical College, Chicago, 1895; aged 63; died, October 13, of cardiovascular renal disease.

**Samuel Logan McCullough**, Oakdale, Pa.; University of the City of New York Medical Department, 1884; aged 83; died, September 4.

**David Lawrence Redmond**, Buffalo; Niagara University Medical Department, Buffalo, 1887; aged 73; died, October 13, of arteriosclerosis.

**George Manuel Dooneief**, Brooklyn; Long Island College Hospital, Brooklyn, 1921; aged 40; died in October, of multiple myeloma.

**William Leonard Vickers**, Rialto, Calif.; Emory University School of Medicine, Atlanta, Ga., 1920; aged 42; died, September 6.

**Starke Hassell**, Miami, Fla.; Jefferson Medical College of Philadelphia, 1886; aged 75; died, October 6, of carcinoma of the prostate.

**Alfred James Parker**, Chicago; Chicago College of Medicine and Surgery, 1913; aged 62; died, October 6, of diabetes mellitus.

**Martin Luther Boyd**, Middle Township, N. J.; Detroit College of Medicine, 1908; aged 55; died, October 3, of tuberculosis.

**Frank Kennedy** \* Goodland, Ind.; Medical College of Indiana, Indianapolis, 1902; aged 57; died, October 4, of heart disease.

**Gottlieb Schick**, Oceanside, Calif.; College of Physicians and Surgeons of Chicago, 1887; aged 80; died, September 20.

**Joseph B. Cassell**, Harriman, Tenn.; Hospital College of Medicine, Louisville, Ky., 1897; aged 63; died in September.

**Charles Lot Browning**, Chico, Calif.; Cooper Medical College, San Francisco, 1894; aged 75; died, September 19.

### BLOOD TYPING METHOD FOR DETERMINING PARENTAGE

*To the Editor:*—In Queries and Minor Notes in THE JOURNAL, October 31, the question is raised as to the efficiency of the blood typing method of determining parentage, together with the dependability and reliability of this method. The Pittsburgh physician also wishes to know about "the weaknesses of the method and the situations in which it is scientifically dependable and reliable."

While the answer cites that the blood tests prove only non-paternity and the admissibility of evidence of blood grouping in the recent decision of the South Dakota Supreme Court, in my opinion more can be said in support of the "dependability and reliability of these blood tests."

It may, for instance, be mentioned that European courts have been using these tests for more than ten years, and Schiff collected 6,665 cases with 546 instances in which a false accusation was made. These figures, which do not include the more recent tests for M and N, must be considerably larger by this time. The courts of Germany, Austria, Denmark, Sweden, Norway, Switzerland and Lithuania recognize these tests; very likely this list of countries is incomplete.

In the United States, only New York and Wisconsin have laws on the statute books since 1935 authorizing their courts to order blood tests in suitable cases. The Wisconsin law, which I sponsored, states that "the results of the test shall be receivable in evidence but only in cases where definite exclusion is established." This makes it clear to the court and jury that the blood tests can prove nonpaternity only; if there is no exclusion, the tests are not accepted as evidence.

I recently framed a bill identical to the Wisconsin law, which is to be submitted to the New Jersey legislature, and Professor Matson writes me that he is preparing such a bill in Montana. There is no doubt that in the near future such laws will be found on the statute books of most or all states.

It is definitely known that the blood properties A and B as well as M and N are constant and readily demonstrable with the aid of suitable reagents. Numerous investigations throughout the world have established not only their hereditary nature but also the exact mechanism of the heredity. The theories for the heredity of the four blood groups and the M and N factors are supported by two independent sets of observations: (1) studies on thousands of families and (2) calculation of gene frequencies determined from the incidence of the serologic types among several races. In other words, the best known geneticists and mathematicians accept these theories as established. Furthermore, to my knowledge, I know of no published reports denying the validity of the observations reported.

At the same time I wish to take this occasion to call attention to the necessity of careful selection, preferably by the local medical societies, of suitably trained experts to perform these tests in those states authorized to accept the results as evidence. While the tests for the four blood groups do not present any technical difficulties, those for M and N require involved serologic procedures for the preparation of specific diagnostic reagents. In the first place, immune serums for M and N must be prepared by several injections of selected blood cells into rabbits. Preliminary tests are required to determine when the antibody for M or N is of sufficient potency. An individual qualified to do this work should have on hand a list of the three sorts of individuals (MN, M and N) in each of at least groups O, B and subgroups A<sup>1</sup> and A<sup>2</sup>. These bloods are required

for the absorptions in the preparation of diagnostic fluids the specificity of which should always be checked on the several varieties of known bloods. It is essential that no specific fluid be employed unless it exhibits potent reactions on sensitive cells; i. e., the difference between bloods possessing and those not possessing a given factor must be very distinct.

Taking these considerations into account, the reliability and value of these blood tests are so well established that American courts are now willing to accept these results as evidence.

PHILIP LEVINE, M.D., Newark, N. J.

### TEACHING PSYCHIATRY TO HOUSE OFFICERS

*To the Editor:*—Today it is generally acknowledged that, in the treatment of many patients, more is accomplished from the recognition and proper management of their mental conflicts than from the diagnosis and treatment of their somatic disturbances; not infrequently in our patients no organic disease is primarily responsible for their complaints. To put it another way, mind plays a large part in the mechanism of illness. All of this calls for a better knowledge of psychiatry on the part of practitioners than most of them have.

How to correct this situation is an important pedagogic problem of today. Better teaching of psychiatry now is being given in our medical schools, but this is not enough.

With a realization that patients at the Peter Bent Brigham Hospital would be better treated if those primarily responsible for their care knew more of the fundamental principles of psychiatry, I sought a means to that end. It was obvious to me that these house officers should have an opportunity to see and follow the management of mental patients in an institution planned for that purpose. How could this be brought about at no cost to the Peter Bent Brigham Hospital?

I took this problem first to Dr. James V. May, commissioner of mental disease of the Commonwealth of Massachusetts, and later to Dr. Winfred Overholser, his successor. Both were willing, actually eager, to cooperate, with the result that they offered to my medical house officers at the Peter Bent Brigham Hospital the opportunity of residence and practical instruction for four months in Massachusetts state hospitals. I incorporated in my medical service of sixteen months an additional period of four months to be spent at one of these state hospitals, the period following a four months experience in clinical laboratory work and preceding clinical service at the Peter Bent Brigham Hospital.

Now this plan has been in operation for a year, two men going to the Boston State Hospital and one to the Worcester State Hospital for each period. What is the result? A noticeable increase in interest in the mental conflicts of our patients and a greatly bettered method of handling their psychiatric problems. It has proved definitely worth while to Brigham patients, and I am sure it will be a continuous help to these house officers in their subsequent practice of medicine. The officers of these institutions have been enthusiastically concerned to see that these house officers learn as much as possible of psychiatry in the available time.

This plan is a practical means of meeting another deficiency in our scheme of educating men to practice a better medicine. Undoubtedly in the long run this plan too will bring a recompense to state hospitals for mental disease in developing practitioners ready to be more cooperative in meeting the enormous problem of the best possible care of patients afflicted with serious mental disease.

HENRY A. CHRISTIAN, M.D., Boston.

Physician-in-Chief, Peter Bent Brigham Hospital.

### "CARE OF THE NEW-BORN INFANT OF THE DIABETIC MOTHER"

To the Editor:—In THE JOURNAL, Sept. 19, 1936, appeared a contribution "Delivery and Care of the New-Born Infant of the Diabetic Mother," by Drs. Lawrence M. Randall and Edward H. Ryncarson of Rochester, Minn. Their observations are of such importance that they should not be overlooked. Their experiences demonstrate the occurrence of certain signs and symptoms associated with hypoglycemia in babies of diabetic mothers. It is not only true, as they suggest, that some deaths in infants born of nondiabetic mothers may be associated with hypoglycemic conditions, but undoubtedly the signs and symptoms such as they describe are rather frequently seen in babies of nondiabetic inheritance.

In their cases there were valid reasons for attributing their etiology to malfunction of the pancreas. In infants of nondiabetic mothers, although as has been reported in the literature the pancreas may be at fault, one will probably as a rule need to look elsewhere for the cause of the disturbances. Although certain of the symptoms may disappear following irradiation over the thymus area, with our present knowledge one can hardly put the blame for the disorders, at least entirely, on the size of the thymus. For the present, we are hardly justified in concluding that the thymus gland functionally has or has not anything to do with the production of the various signs and symptoms under discussion.

The idea (Petersen) that the effects of the roentgen rays are those of nonspecific protein reactions points to the vegetative nervous system and to the endocrines as possible if not probable etiologic factors. In my experience, the theory involving hypocalcemia (tetany of the new-born), as a primary etiologic factor will seldom hold, either in the laboratory or therapeutically. The same is true of considering cerebral edema as a primary factor in the production of the symptomatology. Furthermore, how can one accurately diagnose cerebral edema (Shannon) in a babe without doing a spinal puncture? Even the ascertained presence of the edema does not of itself give the cause of the edema. Experience has convinced me of the truth of the statement "The symptoms of cerebral edema and anemia are the same" (McLeod). Newer information tends to indicate that the vitamin-B complex deficiency conjecture (Dennett, Moore) may not be so far different from the imbalanced neuro-endocrine (vagotonia) hypothesis (Aldrich).

In Randall and Ryncarson's cases a true hyperinsulinism gives a valid reason for the hypoglycemia and associated symptoms. In the disorders of infants of nondiabetic mothers which simulate those which these authors describe, a hyperinsulinism is probably present. The hyperinsulinism is, however, probably a relative one rather than a true one. In other words, in many of the cases, if not in the majority of them, the hypoglycemia and symptomatology may very probably be due to a hypoactivity of the sympathetic system rather than to an actual hyperactivity of the parasympathetic system.

There are several good reasons why one may believe that such a disturbed neurohormone balance may be an important etiologic factor in the occurrence of these peculiar clinical syndromes in certain babes. In the first place, the mothers of these little patients frequently manifest evidences of an endocrine abnormality, particularly of the thyroid. The physiologic postnatal involution of the adrenals and the early inactivity of the infant's thyroid, either or both of which may be exaggerated in those infants whose inherent constitutional weakness (diatheses) may probably cause certain ones to be abnormally sensitive to their environmental stimuli in my opinion, supply a suitable basis for the origin of the disorders under discussion. Furthermore, that this hypersensitiveness may persist in later life in some individuals is manifested by allergic disorders, susceptibility to infections, and obvious endocrine diseases. Finally,

the usual finding of a hypoglycemia and the consistent relief of the signs and symptoms following treatment based on the neuro-endocrine hypothesis should be pretty convincing evidence. So many things may affect the dextrose metabolism of infants that one cannot depend too much on the blood-dextrose tests. Experience has convinced me of that. Randall and Ryncarson's cases also demonstrate that a hypoglycemia may not necessarily be found. They believe as I do that the history, the clinical results and a therapeutic test are of more value, especially after other possibilities, particularly anatomic disturbances, have been eliminated as nearly as possible. When one has had, as I have had, during the past seven years, the repeated experience of seeing cases of the kind we are discussing effectively relieved following the administration of whole adrenal gland, and at times thyroid gland with appropriate feeding (*Illinois M. J.* 61:345-355 [April] 1932; *Arch. Pediat.* 53:851-866 [Dec.] 1933; *M. Rec.* 140:189-193 [Aug. 15] 1934; *Illinois M. J.* 70:244-250 [Sept.] 1936), one can hardly ignore such observations.

Just a word or two more. On page 997 of the same issue of THE JOURNAL which contains Randall and Ryncarson's article there is an abstract (Thymic Death and Meteorological Environment) by Dr. S. A. Levinson which is particularly pertinent. Finally, D. B. Calvin (*Proc. Soc. Exper. Biol. & Med.* 34:724 [June] 1936) has recently presented experimental observations which are very apropos.

ORVILLE BARBOUR, M.D., Peoria, Ill.

### Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

#### TESTS FOR SYPHILIS IN BLOOD DONORS

To the Editor:—What is considered the most practicable test for syphilis among prospective donors of blood to use in a little town? I have the equipment for taking and giving the blood but no way of determining the Kahn reaction except by mailing specimens to Jacksonville, Fla. I can be of real service here if I can give transfusions, as most of the people cannot afford hospitalization in West Palm Beach or elsewhere and no county organization will put up the money. I can construct shaker and water bath or other equipment but have forgotten the details of the Kahn test, which I suppose is the most likely test to be set up at small expense (granted I make a little equipment). Collections are too small for me to buy any such equipment as La Motte's for the "Kline Slide Test for Syphilis." And so if you could send me a protocol for an applicable test under the conditions in this city and suggest a drug house which sells in the region, I would appreciate it greatly. I am going to expose myself to the charge of radicalism by suggesting that there may be some method of applying neosphenamine to a prospective donor's blood, either before withdrawal or in vitro, which would render it innocuous from the standpoint of transmitting syphilis. Perhaps some work has been done already along this line.

G. J. POTTER, M.D., Clewiston, Fla.

ANSWER.—The Kahn test is generally considered practicable for testing the blood of prospective donors for blood transfusion. But any test for syphilis requires, for dependable results, expert knowledge in its performance.

Reagents for performing a Kahn test consist of (1) standard Kahn antigen, (2) physiologic solution of sodium chloride and (3) the blood serum to be tested, obtained by permitting the withdrawn blood to clot and by separating the serum from the clot after centrifugation. This serum is heated for thirty minutes in a water bath at 56 C. and is then ready for use in the test.

Equipment for performing a Kahn test consists of (1) two antigen vials for mixing the antigen with physiologic solution of sodium chloride, (2) a 0.2 cc. pipet graduated in 0.001 cc. for measuring the antigen-saline suspension, (3) three test tubes about 1 cm. in diameter and 7.5 cm. in height, (4) a 1 cc. pipet graduated in 0.01 cc. for measuring the serum to be tested, and (5) a test tube rack.

In performing the test the first step is to prepare the antigen-saline suspension. The amounts of antigen and physiologic solution of sodium chloride to use depend on the "titer" of

the antigen and are indicated on the label of the antigen bottle. The required amount of salt solution is measured into one of the antigen vials and the antigen in the other vial. The salt solution is poured into the antigen and the mixture poured rapidly back and forth one vial into the other about six times to assure thorough mixing. The antigen-saline suspension is permitted to stand for ten minutes. After this period, the following three quantities of the suspension are measured by means of the 0.2 cc. pipet into the three test tubes: 0.05 cc. into tube 1, 0.025 cc. into tube 2 and 0.0125 cc. into tube 3. These quantities are deposited in each case to the bottom of the tubes. To each tube is then added 0.15 cc. quantities of the heated serum, and the rack is shaken to permit thorough mixing of the serum with the antigen suspension. The rack is now shaken for a three minute period, either by means of a shaking apparatus or by hand. This step is followed by adding 1 cc. of salt solution to tube 1 and 0.5 cc. to tubes 2 and 3. After mixing, it will be found that, if the serum tested came from a nonsyphilitic person, no visible precipitate will be present, but if the serum came from a syphilitic person, a precipitate will be suspended in the fluid. Marked precipitation in the tubes is read four plus; weaker precipitation is read three plus, two plus, one plus or doubtful, depending on the degree of precipitation. The final result of the test represents the average reading of the three tubes. Thus, the Kahn reaction is reported four plus if each of the three tubes gives a reading of four plus. If the readings in the three tubes are negative, two plus, four plus, the final reaction is two plus. When testing the serum of a donor, it is necessary at the same time to test also several control serums, both of nonsyphilitic and of syphilitic origin.

Standard Kahn antigen for this purpose will undoubtedly be furnished by the State Health Department Laboratories at Jacksonville, although it may be obtained also from any of the representative biological houses.

The suggestion of mixing a prospective donor's blood with nearsphenamine is an interesting one. It would, however, require extensive research to determine the quantities of this drug to employ with given amounts of syphilitic blood containing definite numbers of spirochetes. It is obviously far simpler and safer to employ blood from nonsyphilitic persons than to attempt to employ "sterilized" blood from those who are syphilitic.

#### GONADOTROPIC SUBSTANCE AND DESCENT OF TESTIS

*To the Editor:*—Will you kindly refer this letter to the writer of the editorial entitled "Clinical Application of Hormones of Anterior Pituitary and Gonads," which appeared in *THE JOURNAL* Oct. 24, 1936? I would like to have such figures and facts as may have been collected in proof of the statement "It is somewhat difficult to find an article reporting the failure to produce descent of the testes by injection of gonadotropic substance, yet many such failures occur." This statement is pertinent to some results in endocrine therapy of cryptorchidism in which I am interested.

JAMES B. HAMILTON, Ph.D., Albany, N. Y.

**ANSWER.**—The sentence quoted from the editorial is a little lost without its context, but the thought was that there is a great deficiency of articles in the literature on the subject of the treatment of undescended testes. The facts are obvious, namely, that the literature is filled with glowing reports and that only rarely can any one find an article reporting failure, yet success does not always attend such efforts. One well known urologist comments on the fact that most of the pictures illustrating such articles showing the condition before and after treatment almost invariably show a well developed scrotum before gonadotropic substances are injected. It has been his experience that in the presence of a well developed scrotum there is almost invariably descent, although sometimes the descent is a little later than is normally seen.

Since the editorial mentioned was published, the Central Society for Clinical Research has met. On that occasion Dr. W. O. Thompson and his associates from Chicago presented a paper entitled "The Present Status of the Treatment of Undescended Testes." The author's abstract says: "In contrast to the large percentage of successful results (70 per cent on the average) reported by various observers in the treatment of undescended testes with an anterior pituitary-like substance, we were able to produce descent in only about 20 per cent of the cases. In four or five cases showing descent, the testis could be pulled to the upper end of the scrotum or nearly to this level before treatment was started. In all successful cases descent occurred within one month, but stimulation of genital growth persisted for a much longer time. In all patients treated surgically after prolonged administration of anterior pituitary-like substance, anatomic factors making descent difficult or impossible were present. However, the stimulation of genital

growth produced by preoperative treatment with this material seemed to make surgical procedures less difficult. It would thus appear that, in the present state of our knowledge, operative procedures are necessary in most cases of undescended testes but should be preceded by from four to six months of treatment with anterior pituitary-like substance."

#### PSYCHASTHENIA IN CHILD

*To the Editor:*—A white boy, aged 13 years, seen in December 1935, refused to attend school because of a burning sensation in the epigastrium, which was present on arising and continued until about 10 a. m. If the boy slept late in the morning there was no discomfort. The burning sensation became worse if he attended school and continued throughout the day. It was decided to have him attend school in the afternoon, but then in the afternoons when he was ready for school a transient diarrhea developed which precluded this. He was a normal, full-term child, who talked at 7 months, teething at 1 year and walked at 16 months. At 5 years of age he had an attack of chorea which persisted until he was 9, when following an acute febrile infection lasting about three weeks he was apparently cured. He was vaccinated at 6. He had frequent sore throats with marked cervical adenopathy. He had enuresis until 11 years of age, which ceased after an attack of chickenpox. At the onset of the chickenpox, he fainted in school. Since then because he frequently had marked flushing of his face, especially when he attempted to read, the teachers sent him home. They were afraid he would faint. About one year ago, he finally refused to attend school. He was sent to another school, but although his behavior was excellent and his grades good the epigastric discomfort ended his attendance. At home he is usually quiet, though he is subject to frequent outbursts of temper when he does not have his own way. He doesn't associate much with other children. His parents are worrisome but apparently in good health. His mother had two miscarriages, at three and five months, prior to the birth of the patient. There is another child, a boy, aged 7 years, who is thin but healthy and active. There is no history of familial or hereditary diseases. The family is of moderate means. The patient is a well nourished, pre-adolescent boy, weighing 95 pounds (43 Kg.). He is unable to sit quiet. He scarcely opens his mouth when talking and his voice is whining in character. The cheeks are flushed at all times. The temperature is normal. The pulse varies from 90 to 110. The systolic blood pressure ranges from 130 to 180 (usually 160) and the diastolic pressure is 80. There is no abnormal fat distribution. The contour of the head is normal. The ears and eyes are normal. There is an occasional purulent discharge from the nose. The teeth and tongue are normal. The tonsils are enlarged. There is a palpable cervical adenopathy. The thyroid is not enlarged. The chest is essentially normal. The heart beat is rapid and forceful, with a presystolic mitral murmur. Peristalsis is hyperactive. There is no tenderness of the abdomen. There are no palpable masses or enlarged organs. The genitalia are normal, preadolescent. Both testicles are descended. The rectum externally is normal. The hands are cold and purplish; there is visible perspiration; there are no tremors. The reflexes are slightly exaggerated. The Babinski reflex is negative. There are no eruptions on the skin. There was axillary sudation during the examinations. There is no tenderness of the back or deformity of the spinal column. The urine is normal. Hemoglobin is 14 Gm. Red blood cells number 4,800,000; white blood cells 5,000; neutrophils 65 per cent; lymphocytes 30 per cent; eosinophils 2 per cent; basophils 1 per cent; myelocytes 2 per cent. The Wassermann reaction of the blood is negative. Tuberculin tests are negative. Roentgenograms of the skull, chest and abdomen reveal a small pituitary fossa, a cardiac silhouette suggestive of mitral disease, enlargement of the spleen and the liver, and coarse trabeculations in the spine and pelvis and ribs. There are no other significant manifestations. Please omit name. M.D., Pennsylvania.

**ANSWER.**—The history of this boy indicates that he is of a neuropathic nature if not of a psychasthenic type. It is significant that he developed normally, talking at 7 months, and equally important is the fact that he had a persistent chorea from the fifth to the ninth year and an acute febrile infection of three weeks' duration. An attack of chorea lasting four years suggests the possibility of an encephalitis at that time, and the present symptoms might be interpreted as postencephalitic behavior disorders. The symptoms such as flushing, cold and purplish hands seem to indicate a lack of vasomotor stability. In the absence of more definite signs one would be inclined to interpret the burning sensation in the stomach as an indication of a gastric neurosis. In addition to the various tests that have already been made it would seem advisable to observe the daily temperature course, to note the presence of tremors and the pulse rate, and to obtain the basal metabolic rate in order to show the presence or absence of a hyperthyroidism. Some stress has recently been laid on the relationship of hypoglycemia to nervous symptoms such as have been described; consequently it might be well to estimate the blood sugar. In view of the possible postencephalitic character of the condition it would be well to repeat all the neurologic tests, including an ophthalmologic examination and a routine visual test.

The management of such a boy as a rule causes anxiety and difficulty for the parents and discomfort to the attending physician. The time comes when he is almost unmanageable in the home. It should not be forgotten that a patient with

such symptoms as this boy presents may develop a genuine psychosis. If the boy could be sent to a school away from home, to a summer camp, or placed in the hands of considerate and intelligent friends, some improvement might result. It would seem that if no tangible evidence of organic or functional cerebral disease can be elicited, it would be in the interest of this boy to seek the advice of a psychiatrist.

#### SURFACE TENSION OF MALIGNANT CELLS

To the Editor:—I am interested in obtaining information regarding the surface tension determinations in malignant cells. Any information, reprints and abstracts covering this subject would be greatly appreciated

ROY J. POPKIN, M.D., Los Angeles.

ANSWER.—The direct determination of surface tension of individual malignant cells cannot be satisfactorily made because such cells when isolated in culture or otherwise can never be considered as existing under the same conditions as they would in the body. A considerable number of studies have been made by determining the surface tension of extracts from cancer cells, but obviously the surface tension so determined cannot be considered as being the same as that of the uninjured cell. A bibliography of pertinent observations, including studies on permeability which is not the same as surface tension necessarily, is appended.

Krebsforsch.* 42: 324, 1935. Significance of surface tension for growth in general and for cancer in particular.

Knake, Else: Ueber die Bedeutung der Permeabilität das Gewebswachstum. *Ztschr. f. Krebsforsch.* 42: 329, 1935. Changes in cell permeability exert an influence on growth.

Heubner, W., and Orezchowski, G.: Permeabilität und Wachstum. Bemerkungen zu der Mitteilung von Else Knake. *Ztschr. f. Krebsforsch.* 42: 329, 1936. Knake and Traube have drawn deductions which are not warranted by their facts.

Kikuchi, T., and Kawanishi, G.: Surface Tension of the Tissue of Uterine Tumor. *Jap. J. Obst. & Gynec.* 18: 340, 1935; abstr. *Am. J. Cancer* 26: 796 (April) 1936, as follows: Many investigators have recorded their determinations of the surface tension of blood or tissue fluids in malignant disease, but not one has stated when the readings were made. Yet, as surface tension decreases with the lapse of time, this is an important point. Taking the factor of time into consideration, the author compared extracts of uterine carcinoma, myoma and chorionepithelioma with those prepared from normal portions of the corresponding uteri, using a Hartmann-Braun torsion balance after Brinkmann's method. Extracts of all three tumors had a surface tension lower than the control preparation. The material examined consisted of ten carcinomas, ten myomas and five chorionepitheliomas.

#### GASTRORRHAGIA

To the Editor:—I have recently had occasion to look after a case of "gastrorrhagia" in a man, aged 26. At the age of 10 years he had the small veins of his nose cauterized because of severe attacks of prolonged epistaxis. Subsequently there were no further attacks of nasal bleeding but at frequent intervals the patient was prostrated by severe gastric hemorrhages, which recurred every two to six months over a period of ten years. All treatment, with the exception of transfusion, failed. The patient was given several transfusions at each attack. (He received eighty-seven transfusions in from five to seven years.) At one time peptic ulcer was suspected (although x-ray examination was negative) and a posterior gastro-entrostomy was done with no apparent benefit. The patient still had attacks of bleeding. Finally, when he was 26 years of age, he died during a severe hemorrhage. All the laboratory examinations gave normal results except for the manifestations of a secondary anemia during the periods of relapse. The platelet counts and clotting and bleeding time tests were all normal. No evidence of blood dyscrasia could ever be demonstrated. At the autopsy all organs were normal except for the stomach, which contained many small punctate erosions in the lining, about 100 in all, from which bleeding had obviously occurred. Under the microscope, these appear merely as small superficial regions of necrosis in the mucosa. I would greatly appreciate information regarding the name of this condition, references to literature and any other pertinent information that you might have. Kindly omit name.

M.D., Washington.

ANSWER.—This is a good description of a disease that perhaps deserves a special name. No description of it appears to have been published but during the last several years a number of cases have been seen. Curiously a number of the victims were physicians. In one of the worst of these cases there was some family history of similar bleeding. One patient was seen to bleed to death, and the necropsy showed absolutely nothing that could be recognized as a bleeding point. In some cases there were some symptoms suggesting ulcer, and in others there were no such symptoms. Operations were futile, as one might expect.

Fortunately, a large percentage of the patients are able to survive many severe hemorrhages. One physician has now gone several years without bleeding, but naturally he lives in constant dread of another attack. In most of the cases expert hematologists were unable to find changes in the blood characteristic of any known disease in which bleeding is common. There has been a suggestion in one or two cases that allergy may be a factor. Naturally, treatment is very difficult when the mechanism of the disease is unknown. In a few cases Dr. Charles Watkins of the Mayo Clinic has found moccasin venom to work beautifully. It deserves further trial. In every case, expert hematologists should be consulted.

#### ETIOLOGY OF GRANULOCYTOPENIA

To the Editor:—Could subjection to gases from burning coals and ashes over about a period of six months be conducive to the production of agranulocytic angina? The coal in question is semianthracite. Kindly omit name if published.

M.D., Pennsylvania.

ANSWER.—The amount and variety of gases given off by burning anthracite coal are dependent on the conditions under which the combustion occurs. If combustion is incomplete it is possible that the smoke and fumes may contain a wide range of compounds, including benzene and the so-called coal tar products. If combustion is complete with an adequate oxygen supply and the residue burned to an ash, it is unlikely that such compounds are given off in appreciable amounts.

Assuming, however, that an individual is subjected to such compounds by inhalation over a period of six months, it is again problematic whether the inhalation of such products could produce agranulocytosis. There is some evidence that it is possible especially if the fumes contain benzene (C<sub>6</sub>H<sub>6</sub>). It has been demonstrated that the injection of benzene does consistently produce the hematologic picture of agranulocytosis in rabbits (Kracke, R. R.: *Am. J. Clin. Path.* 2: 11 [Jan.] 1932). However, when rabbits are subjected to inhalation of this chemical, no hematologic changes result. It would appear that a pulmonary defensive mechanism prevents its development.

Furthermore, leukocytic depression has not been observed often in workers who inhale benzene for many years (Hamilton, Alice: Industrial Poisoning, New York, Macmillan Company, 1925).

To summarize, it appears possible that such conditions could be conducive to the production of agranulocytosis. It would depend on the type of fumes given off, and on the presumption that the inhalation of these could so depress the hematopoietic centers as to result in leukocytic depression. The entire question is one that deserves investigation by those who work in the field of industrial medicine.

#### PERFUMES AND ORRIS ROOT—CHICLE—PEANUT BUTTER AND SOY BEAN—"SPRY"

To the Editor:—1. Are there any perfumes on the market that can be safely used by a patient sensitive to orris root? 2. What are the ingredients of Wrigley's chewing gum to which an allergic patient might be sensitive? 3. Does most peanut butter contain soy bean? Can you give me the name of some brand that does not? 4. Can you tell me the ingredients of the shortening "Spry"?

LOUISE O. KAPPES, M.D., Evanston, Ill.

ANSWER.—1. Orris is used in cosmetics as an absorbing agent for perfumes. Patients sensitive to orris root are not necessarily sensitive to perfumes. If such sensitivity is present, its determination is a specific problem in each individual case and for each perfume.

2. The main ingredient in all chewing gums is chicle. Chicle sensitivity is not common but has been described. Sensitivity to other substances used for flavoring, as peppermint or spearmint, is likewise uncommon.

3. Peanut butter, if so labeled, does not contain any soy bean product unless it is used as an adulterant. If contained in this product this should be stated on the label in accordance with the Food and Drug regulations.

4. The composition of the shortening "Spry" is a trade secret. Most shortenings on the market are composed of hydrogenated cottonseed oil. Hydrogenated coconut oil and corn oil are frequently mixed with this.

#### FUNCTIONAL VOMITING

To the Editor:—A white woman, aged 28, married, a high school teacher, presents the chief complaint of nausea and vomiting at frequent intervals over a period of six months. She has been susceptible to car sickness and sea sickness for about six years, but prior to the present illness there was no history of apparently causeless vomiting. Her appendix was removed in 1921, and in 1932 an operation was performed for a cystic ovary, at which time some adhesions from the previous operation were released. Following the second operation she experienced severe vomiting for three days and nights, which stopped suddenly, and the convalescence was otherwise uneventful. In November 1935 she began to be nauseated at frequent intervals, often with vomiting, and principally in the morning. At one time she was in bed for a week, and at times the vomiting was "almost constant." It seems to be brought on by excitement. Nausea is definitely relieved by lying down, to a less extent by vomiting, and is made worse by eating. She has been married for eight months but has had no menstrual irregularity at any time and presents no indications of pregnancy. Recently she also complained of a slight evening rise of temperature—to about 99.6 F. Physical and x-ray examinations of the chest are negative. Fluoroscopic examination of the stomach shows an organ hanging well below the iliac crests. When she first swallowed the barium it seemed as though there was a constriction between the fundus and the dependent portion, but this opened up as more barium was taken. After an hour the barium had collected in the dependent portion, and almost none had passed into the duodenum. We have advised more frequent feedings of a nonirritating nature, support and atropine. It is too soon to tell whether this will bring any results, but we are anxious to have any help that is available.

M.D., Virgin Islands.

ANSWER.—The impression gained from the history is that the woman is suffering with some type of functional vomiting or regurgitation. It would help greatly to know whether the trouble is regurgitation rather than vomiting. With nervous regurgitation mouthfuls of food begin to come up often before the patient leaves the table, and there is no complaint either of nausea or of retching. This syndrome is a definite clinical entity, and the cause must be a nervous one because operations are practically always useless, even when a gallstone or a diseased ovary or suspicious looking appendix can be found on abdominal exploration.

It would be most helpful to find out whether this woman is entirely satisfied with her marriage or if she is much afraid of pregnancy. Treatment should consist mainly of rest and psychotherapy. The patient should understand that she must make a big effort to keep food down. Otherwise, the regurgitation increases in severity like a bad habit. Rest in bed often

helps. Sometimes feeding by stomach tube helps if the patient knows that this will be discontinued when she learns to hold her food down. Sedatives may have to be used. A dry type of diet may be helpful, the patient taking necessary liquids between meals.

If the patient keeps a record she may find that some one food is regurgitated more than others are and the removal of such food from the diet may bring considerable relief. The giving for two days of an elimination diet consisting of only lamb and rice will often tell whether modification of the diet will help at all.

Constipation should be avoided since the stagnation of material in the colon can produce back pressure in the small bowel, and this increases the tendency to regurgitation. The best way of relieving constipation may be to give a daily enema of physiologic solution of sodium chloride.

In order to succeed with treatment the physician must not waver in his diagnosis; he must not get to wondering out loud whether there might be some lesion present in the abdomen to account for the trouble. As was said before, even when lesions are present they do not produce or even influence the typical syndrome of regurgitation immediately after meals.

#### BENZENE POISONING

To the Editor:—I am treating a man, aged 45, who has an aplastic anemia due to benzene poisoning. He has had whole blood transfusions of matched and typed blood by the Vincent tube method. He does not respond to liver diet, diluted hydrochloric acid or pentnucleotide. What more can I do with reason and safety? The man is in a hospital where we may have every help. Kindly give reference to reports from THE JOURNAL.

C. R. LEWIS, M.D., Akron, Ohio.

ANSWER.—The chief therapeutic measure in the management of benzene poisoning is transfusion, either with whole blood or with citrated blood. The citrated blood method has the advantage that cutting down on the vein is not necessary and that preservation of a vein for repeated transfusions is possible. It is important to transfuse primarily to control bleeding and not simply for anemia. The beneficial effect of transfusion on the hemorrhagic tendency may last from two to five days. Mechanical means of controlling bleeding, such as packing the nose, are dangerous, as tissue ischemia, necrosis and secondary infection may easily occur with the neutropenia common in benzene poisoning. No specific benefit will be obtained from any type of substitution therapy, such as the use of liver, stomach, iron or vitamin preparations. However, to assure optimal conditions for blood production, the oral administration of iron and liver or stomach preparations should be carried out. Parenteral liver extract is undesirable because of the increased possibility of infection at the site of injections if neutropenia is present. Pentnucleotide may be used but probably has no specific benefit in this condition and again demands injection. If severe neutropenia and secondary sepsis do not occur and bleeding can be controlled by frequent transfusions, there is a good possibility that after a time the bone marrow will begin to supply more red cells, granulocytes and platelets, and therefore anemia, leukopenia and purpura will be diminished. A normal erythrocyte count will ordinarily not be regained before many weeks or until erythrocyte production has returned to a normal level. Patients with severe neutropenia and/or fever usually, but by no means invariably, have a poor prognosis.

#### VITILIGO

To the Editor:—A Mexican, aged 28, had a nervous breakdown a year ago. Two months after the breakdown, disseminated spots of white depigmentation broke out on the skin on the left side of the neck. His weight is around 200 pounds (91 Kg.). I have tested all the reflexes and found all responding and in normal condition. I have diagnosed the condition as vitiligo. Please state whether this diagnosis is correct; also the best and most accepted treatment in such cases. Please omit name.

M.D., California.

ANSWER.—The occurrence of "disseminated spots of white depigmentation" with the absence of atrophy in the patches is called vitiligo, or acquired leukoderma.

The specific etiology of vitiligo is unknown, and it has been attributed to neurotic disturbances, trophoncrosis, endocrine disturbances and hereditary defects. It may follow or be associated with other dermatoses.

The course is slow, chronic and usually progressive. No specific effective therapeutic agent has been found to date. Locally, the surrounding skin may be bleached with 5 to 10 per cent ammoniated mercury ointment or 10 per cent hydrogen peroxide in anhydrous wool fat and petrolatum. The bathing

of the depigmented patches with 10 per cent of oil of bergamot in alcohol, and subsequent exposure of the site to ultraviolet rays or strong sunlight, is sometimes effective in increasing pigmentation of the sites. Gold sodium thiosulfate, intravenously (Lindsay, H. C. L.: Treatment of Leukoderma with Gold Sodium Thiosulfate, *Arch. Dermat & Syph.* 20:22 [July] 1929) has been used in some of these cases. Its use, however, has produced variable results in different hands.

#### ETHYL ACETATE AS INDUSTRIAL HAZARD

*To the Editor:*—I have recently received a communication stating that an industrial concern has started using ethyl acetate (acetic ether) in one of its production lines to dissolve the surface of a cellulose lens. This is done for the purpose of making the lens adhere to a metal surface. The fumes are very strong and the question is whether fumes from ethyl acetate when applied to a cellulose lens are harmful to the operators performing the work.

MERRILL S. DAVIS, M.D., Marion, Ind.

**ANSWER.**—Ethyl acetate ( $C_4H_8O_2$ ) is relatively unimportant as a toxic agent. This substance is widely used as a constituent of lacquers, solvents, thinners and other coating materials. Skin contact has led to occupational dermatitis, and its vapors are known to be a minor irritant to the eyes and the respiratory tract. This agent has been investigated by H. F. Smyth and H. F. Smyth Jr. (Inhalation Experiments with Certain Lacquer Solvents, *J. Indust. Hyg.* 10:261 [Oct.] 1928). From their animal experiments no evidence developed indicative of marked toxic properties. It is believed that ethyl acetate is scarcely more culpable as a dangerous industrial material than is the more widely used amyl acetate—"banana oil." If arbitrarily the toxicity of benzene is fixed at 100, the order of toxicity of ethyl acetate may be associated with the figure of 10. Ethyl acetate is not extensively used as a single solvent or a thinner but more often is found as one of several constituents in coating materials. In the instance mentioned in the query, due inquiry should establish that ethyl acetate alone is used. If employed along with benzene and toluene, these other agents are to be regarded with greater apprehension as sources of harm to exposed workers. If in fact ethyl acetate is used as the sole agent, and as a substitute for the more toxic hydrocarbons, this procedure is to be commended. Nevertheless, apart from toxic properties, the discomforting effects of these vapors may be such as to warrant general ventilation.

#### PERSISTENT SUBNORMAL TEMPERATURE

*To the Editor:*—What conditions would cause a persistent subnormal temperature of 97 to 98 F., with a slow pulse of from 55 to 65? The patient suffers from marked constipation and has nightly dreams of holdups and murders. His blood pressure is 120 systolic, 90 diastolic. The patient is 48 years old, 5 feet 10 inches (178 cm.) tall and weighs 192 pounds (87 Kg.). He has a good appetite and is physically in excellent shape except that at times he tires easily. The heart, kidneys and lungs are normal. He looks very healthy. Please omit name.

M.D., California.

**ANSWER.**—An electrocardiographic study and determination of the basal metabolic rate should be undertaken. If both of these are normal, the subnormal temperature and slow pulse can probably be accepted as simple variations from the normal, in view of the statements about the general health of the patient. H. A. Reimann (Habitual Hyperthermia, *Arch. Int. Med.* 55: 792 [May] 1935) has shown that approximately 10 per cent of the normal population has a body temperature less than 98 F. Bradycardia is not uncommonly noted in individuals without any apparent disease. The very slight possibility of hypoglycemia (Ormond, A. P.: Bradycardia Due to Spontaneous Hypoglycemia, *THE JOURNAL*, May 16, 1936, p. 1726) may be considered.

#### SALIVATION WITH DENTURES

*To the Editor:*—Please send me information for treatment of excessive salivation due to false teeth. Please omit name.

M.D., Illinois.

**ANSWER.**—Excessive salivation after the placing of dentures is not uncommon. It may have a reflex origin from irritation of the denture or it may be purely psychologic. First, the denture should be carefully examined to determine that there are no technical defects. It should be specially noted, first, that the periphery of the denture is not improperly placed; secondly, that there are no areas of excessive pressure on the mucous membrane; thirdly, that the occlusal plane is properly placed. The improper placing of the occlusal plane, that is, the opening of the bite, will cause disturbances in the tension of the muscles

of mastication and abnormal relations in the temporal mandibular articulation, either of which may cause reflexes affecting the flow of saliva.

Probably the commonest cause is purely this: The consciousness of the dentures in the mouth and the adjustment to the new dentures excite the flow of saliva. The best treatment is the use of a mild sedative, such as medium doses of potassium bromide. Small doses of atropine for a very short time are sometimes effective.

It should of course be determined that there is no other cause for the salivation.

#### PSYCHIATRIC DEFINITIONS

*To the Editor:*—Please define, for psychiatric purposes, level, mood, sensorium, insight, judgment, and stream of talk.

WILLIAM J. O'DONNELL, M.D., Buffalo.

**ANSWER.**—Level: The sphere in which a tendency expresses itself, particularly with relation to development toward (a) consciousness and (b) adult activity.

Mood: A moderate emotion of relatively long duration caused by an unconscious tendency which colors conscious impressions.

Sensorium: The group of sensory receptors and their pathways to conscious and subconscious cortical centers.

Insight: Conscious intellectual and emotional understanding.

Judgment: The capacity to arrive at a view by relating ideas or situations through a process of reasoning.

Stream of talk: The verbal productivity of the patient (characterized as to such traits as rate, coherence or content).

#### COMBINED INFECTION OF THROAT

*To the Editor:*—I have recently treated a severe case of throat infection in which there was a superficial ulceration of both tonsils, which were covered with a gray filmy looking exudate from which hemolytic streptococci were recovered. There was marked adenitis and peritonsillar edema. The uvula was markedly edematous. A competent throat specialist was called in consultation and an incision was made into the edematous peritonsillar tissue, but no pus was obtained. A smear was taken at the same time, which showed the presence of Vincent's organisms. The next day the patient appeared better and was able to swallow without much difficulty. However, the consultant administered 5 cc. of 1 per cent solution of antimony and potassium tartrate, intravenously, which was subsequently repeated twice. It was felt by the consultant that this treatment was specific for Vincent's infection. I have been unable to find anything in the literature concerning this treatment and am wondering if you can give me any information as to its rationale. My impression was that the major part of the picture was produced by the presence of the streptococcal infection and that the Vincent organisms probably played a minor part. Kindly omit name.

M.D., Virginia.

**ANSWER.**—Some additional information concerning the case described might be obtained through a report of the blood picture present. It may be that the correspondent is right in his impression that the major part of the picture was produced by the streptococcal infection, particularly as the importance of Vincent's organism in the production of disease is not clear at present.

Antimony has been used in a number of difficult infections and is reported to be of particular value in granuloma inguinale, which is thought by some to be due to a filtrable virus.

#### HUMIDIFICATION AND CLIMATE IN SINUS DISEASE

*To the Editor:*—There seems to be considerable confusion about the harmfulness of the lack of proper room humidification in sinus and bronchitic conditions. Both the steam kettle and the more modern electric humidifier are recommended to increase the water content of the air for these conditions, in spite of the fact that nearly all physicians recommend the dry climate of the Southwest, where the air humidity compares with that of the average unhumidified apartment in New York in the winter time. I would like very much to get an authoritative opinion on this inconsistency. Please omit name.

M.D., New York.

**ANSWER.**—Fundamental differences exist between the atmospheric conditions of the Southwest and of the larger Northern cities. While the atmosphere is termed that of a "dry climate," there is an appreciable amount of humidity in its air. The sunlight, however, is unfiltered by the usual pall of smoke and soot screen. This and the gentler temperature ranges with other fundamental factors are the determinants in selecting the Southwest as a more suitable climate for those afflicted with "sinus" and "bronchitic" conditions.

Obviously the unfortunate afflicted cannot all avail themselves of a sojourn in the recommended region. Hence the use of the steam kettle or the modern electric humidifier to increase the water content of the air is the alternative.

When the air which this type of patient inhales is properly humidified, there is less crust formation, and the secretions become softened and moistened, and are more easily removed from the air passages by the patient.

Thus it is seen that there is no actual inconsistency in recommending a change of climate to that of the Southwest, and advising that the air of the room habitually used by the patient be humidified for those who are compelled to stay at home.

#### TRAUMATIC DISABILITY OF NOSE

*To the Editor:*—I should like information on traumatic disability of the nose. I would particularly like to know the ways and means of estimating disability due to various traumas. I have a complete library on the nose but cannot find this subject.

JOSEPH J. GRIMM, M.D., South Milwaukee, Wis.

**ANSWER.**—Trauma to the nose may result in disability arising from deformity of the nasal septum by (1) obstruction to respiration, (2) interference with the drainage from the sinuses with resulting stasis and infection of one or more sinuses, and (3) obstruction to the olfactory portion of the nose resulting in the loss of the sense of smell. The disability arising from any of these conditions can be estimated only individually by the inconvenience occasioned.

#### MONGOLIAN IDIOCY

*To the Editor:*—I have been treating a family whose first child was a mongolian idiot, living only a few days. They are naturally fearful of having another child. Can you give me some statistics as to the possibilities of similar trouble with another child? Both parents have average inheritance, are in good health and there is no history of alcoholism. Please omit name.

M.D., Nebraska.

**ANSWER.**—Most careful observers of mongolian mental defectives have been of the belief that this condition occurs but once in a family. One reliable observer lists 322 cases with never a repetition in the same family. There have been a few cases reported in the literature of two or even more with this condition occurring in siblings. The prognosis, therefore, that the next child in the present family would not be a mongolian mental defective is extremely good.

#### HAGEDORN-JENSEN METHOD FOR SUGAR DETERMINATION

*To the Editor:*—In *Queries and Minor Notes* in the Oct. 24, 1936, issue of *THE JOURNAL*, the reply to Dr. Lewis's request for a description of the Hagedorn-Jensen method for blood sugar determination includes standardization of the two hundredth normal thiosulfate solution.

As standardization of the thiosulfate solution involves the use of an oxidizing agent, I feel that there is an error in the use of two hundredth normal potassium iodide solution for this standardization. I would suggest the use of the word "iodate" for "iodide."

Gradwohl's book "Clinical Laboratory Methods and Diagnosis" also gives a standard potassium iodide solution for titration of the two hundredth normal thiosulfate solution.

My personal experience has been that the actual test and blank titrations work correctly but that the standardization of the two hundredth normal thiosulfate solution with a standard potassium iodide solution is not possible.

ETTA SELSAM, M.D., Terre Haute, Ind.

#### CLOSED FONTANELS

*To the Editor:*—In *THE JOURNAL*, October 31, in *Queries and Minor Notes* there is a question concerning the early closure of the fontanel. About twelve years ago I delivered an infant that was normal in every way except that the fontanel was completely closed and the skull appeared to be as firm and solid as an adult's. Being greatly concerned about the baby's future development, I called in a well known brain specialist, who gave a very grave prognosis indeed.

I have recently seen the child again and was pleased to note that he had developed normally in every way. His head is of average size but has a peculiar shape. The cranium is narrow and the forehead, instead of being flat or curving, is roughly wedge shaped. However, the mother claims that this is a family characteristic.

EDITH E. JOHNSON, M.D., Palo Alto, Calif.

#### CARE OF COLLODION

*To the Editor:*—After occasionally finding a bottle of collodion dried up when I wanted to use it, I discovered a method of preventing this annoyance. Collodion can be kept in perfect condition indefinitely by the simple procedure of inverting the bottle for a second or two each time the cork is replaced. This allows the collodion to run into the neck of the bottle and form a film on and around the under side of the cork. This prevents evaporation.

WALTER J. ROBBINS, M.D., New Britain, Conn.

## Medical Examinations and Licensure

### COMING EXAMINATIONS

#### STATE AND TERRITORIAL BOARDS

ALABAMA: Montgomery, June 29-July 1. Sec., Dr. J. N. Baker, 519 Dexter Ave., Montgomery.

ALASKA: Juneau, March 2. Sec., Dr. W. W. Council, Juneau.

ARIZONA: Phoenix, Jan. 5-6. Sec., Dr. J. H. Patterson, 826 Security Bldg., Phoenix.

COLORADO: Denver, Jan. 5. Sec., Dr. Harvey W. Snyder, 422 State Office Bldg., Denver.

CONNECTICUT: *Basic Science*. New Haven, Feb. 13. *Prerequisite to license examination*. Address State Board of Healing Arts, 1895 Yale Station, New Haven.

DELAWARE: Dover, July 13-15. Sec., Medical Council of Delaware, Dr. Joseph S. McDaniel, Dover.

DISTRICT OF COLUMBIA: Washington, Jan. 11-12. Sec., Commission on Licensure, Dr. George C. Ruhland, 203 District Bldg., Washington.

IDaho: Boise, April 6. Commissioner of Law Enforcement, Hon. Emmitt Pfost, 205 State House, Boise.

ILLINOIS: Chicago, Jan. 26-28. Superintendent of Registration, Department of Registration and Education, Mr. Homer J. Byrd, Springfield.

INDIANA: Indianapolis, June 22-24. Sec., Board of Medical Registration and Examination, Dr. William R. Davidson, 301 State House, Indianapolis.

IOWA: *Basic Science*. Des Moines, Jan. 12. Sec., Prof. Edward A. Benbrook, Iowa State College, Ames.

MICHIGAN: Ann Arbor and Detroit, June 9-11. Sec., Board of Registration in Medicine, Dr. J. Earl McIntyre, 202-3-4 Hollister Bldg., Lansing.

MINNESOTA: *Basic Science*. Minneapolis, Jan. 5-6. Sec., Dr. J. Charnley McKinley, 126 Millard Hall, University of Minnesota, Minneapolis. *Medical*. Minneapolis, Jan. 19-21. Sec., Dr. Julian F. Du Bois, 350 St. Peter St., St. Paul.

MONTANA: Helena, April 6. Sec., Dr. S. A. Cooney, 7 W. 6th Ave., Helena.

NEBRASKA: *Basic Science*. Omaha, Jan. 12-13. Director, Bureau of Examining Boards, Mrs. Clark Perkins, State House, Lincoln.

NEVADA: *Reciprocity*. Carson City, Feb. 1. Sec., Dr. John E. Worden, Carson City.

NEW HAMPSHIRE: Concord, March 11-12. Sec., Board of Registration in Medicine, Dr. Charles Duncan, State House, Concord.

NEW JERSEY: Trenton, June 15-16. Sec., Dr. James J. McGuire, 28 W. State St., Trenton.

NEW MEXICO: Santa Fe, April 12-13. Sec., Dr. Le Grand Ward, Box 693, Santa Fe.

NEW YORK: Albany, Buffalo, New York and Syracuse, Jan. 25-28. Chief, Professional Examinations Bureau, Mr. Herbert J. Hamilton, 315 Education Bldg., Albany.

NORTH DAKOTA: Grand Forks, Jan. 5-8. Sec., Dr. G. M. Williamson, 4½ S. 3rd St., Grand Forks.

OREGON: Portland, Jan. 5-7. Sec., Dr. Joseph F. Wood, 509 Selling Bldg., Portland.

PENNSYLVANIA: Philadelphia, Jan. 5-9. Sec., Board of Medical Education and Licensure, Mr. James A. Newpher, Education Bldg., Harrisburg.

PUERTO RICO: San Juan, March 2. Sec., Dr. O. Costa Mandry, Box 536, San Juan.

RHODE ISLAND: Providence, Jan. 7-8. Chief, Division of Examiners, Mr. Robert D. Wholey, 366 State Office Bldg., Providence.

SOUTH DAKOTA: Pierre, Jan. 19-20. Dir., Division of Medical Licensure, Dr. B. A. Dyar, Pierre.

VERMONT: Burlington, Feb. 10-12. Sec., Board of Medical Registration, Dr. W. Scott Nay, Underhill.

WASHINGTON: *Basic Science*. Seattle, Jan. 7-8. *Medical*. Seattle, Jan. 11-13. Dir., Department of Licenses, Mr. Harry C. Huse, Olympia.

WEST VIRGINIA: Charleston, March 1. Sec., Public Health Council, Dr. Arthur E. McClue, State Capitol, Charleston.

WISCONSIN: Madison, Jan. 12-14. Sec., Dr. Henry J. Gramling, 2203 S. Layton Blvd., Milwaukee.

WYOMING: Cheyenne, Feb. 1. Sec., Dr. G. M. Anderson, Capitol Bldg., Cheyenne.

#### NATIONAL BOARD OF MEDICAL EXAMINERS

NATIONAL BOARD OF MEDICAL EXAMINERS: *Parts I and II*. Feb. 9-11, May 10-12, June 21-23, and Sept. 13-15. *Part III*. New York, Jan. 11-13 and Chicago, Jan. 19-21. Ex. Sec., Mr. Everett S. Elwood, 225 S. 15th St., Philadelphia.

#### SPECIAL BOARDS

AMERICAN BOARD OF DERMATOLOGY AND SYPHILOLOGY: *Written examination for Group B applicants* will be held in various cities throughout the country, April 17. *Oral examinations for Group A and B applicants* will be given in Philadelphia, June 7-8. Sec., Dr. C. Guy Lane, 416 Marlborough St., Boston.

AMERICAN BOARD OF INTERNAL MEDICINE: *Written examination* will be held simultaneously in different centers of the United States and Canada on December 14 and in March. *Practical examination* will be given in St. Louis in April and at Philadelphia in June. Chairman, Dr. Walter L. Biering, 406 Sixth Ave., Rm. 1210, Des Moines.

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY: *Written examination for Group B applicants* will be held in various cities throughout the United States and Canada, March 6. *Practical, oral and clinical examinations for Group A and B applicants* will be held at Atlantic City, N. J., June 7-8. *Applications must be received at least sixty days prior to the examination dates*. Sec., Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh (6).

AMERICAN BOARD OF OPHTHALMOLOGY: Los Angeles, Jan. 23. Sec., Dr. John Green, 3720 Washington Blvd., St. Louis, Mo.

AMERICAN BOARD OF ORTHOPAEDIC SURGERY: Cleveland, Jan. 9. Sec., Dr. Fremont A. Chandler, 180 N. Michigan Ave., Chicago.

## Book Notices

**A Preface to Nervous Disease.** By Stanley Cobb, A.B., M.D., Bullard Professor of Neuropathology, Harvard Medical School. Cloth. Price, \$2.50. Pp. 173, with 13 illustrations. Baltimore: William Wood & Company, 1936.

This is an excellent treatise written by an able neuropsychiatrist, who briefly discusses facts and correlations that are necessary in order to understand the simpler workings of the central nervous system. Anatomic, physiologic and pathologic data are closely correlated and the reader gets only the known and proved facts. The book is divided into twelve chapters, the autonomic nervous system, the cerebrospinal nervous system, motor integration and locomotion, functional localization in the cerebral cortex, consciousness and the "mind-body" problem, the cerebral circulation, the cerebrospinal fluid, paths of infection to the nervous system, general histologic pathology, the peripheral nerves and neuritis, special histologic pathology, and epilepsy and the psychoses. The author illustrates the relationship between psychiatry and certain other sciences. Psychiatry is represented as a pyramid, its apex being philosophy and its base physics, chemistry and anatomy. Above the latter three named are physiology, neurology and experimental psychology. Between these and the apex (philosophy) there exists a space which at present is a void and which requires intensive research in the future in order that facts may be found to explain the observations and to support satisfactorily the theories now being discussed in psychiatry and psychology. The bibliography, unfortunately, is brief. The book is recommended to all neuropsychiatrists.

**Handbuch der experimentellen Pharmakologie.** Begründet von A. Heffter. Ergänzungswerk. Herausgegeben von W. Heubner, Professor der Pharmakologie an der Universität Berlin, und J. Schüller, Professor der Pharmakologie an der Universität Köln. Band 11: Narkotiken der Fettsäure. Von M. Koelmann. Paper. Price, 36 marks. Pp. 283, with 29 illustrations. Berlin: Julius Springer, 1936.

This supplement is intended to bring down to date the chapter on "Narcotics of the Fatty Series" of volume 1 of the "Handbuch der experimentellen Pharmakologie." Kochmann summarizes the present status of anesthetics as follows: Chloroform, on account of its intrinsic dangers, is being largely abandoned. Ether is preferred, but not by itself. It is used in combination with other narcotics ("mixed narcotics"). "Pre-narcosis" is the term to be applied to the use of a narcotic to make easier the induction of anesthesia, while a "basis narcotic" is one that carries the main burden of an anesthesia, to be completed by a more controllable anesthetic. Kochmann believes that ether as well as local anesthesia is likely to become largely displaced by the gases and by briefly acting intravenous anesthetics. There are intrinsic reasons why the gas anesthetics are safer than ether or chloroform. The latter must be administered at the beginning in toxic concentration, because of their slowness in inducing anesthesia. Gas anesthetics may be given in safe concentration from the beginning, because of the promptness with which they act. This is due to the relative insolubility of the gas, as compared with relative solubility of ether or chloroform. Narcosis occurs in spite of this relative insolubility because of the high partial pressure of the gas that can and must be maintained in the lungs. The highest gas concentration that can be maintained at atmospheric

pressure in the lungs with acetylene, ethylene or nitrous oxide is below the fatal limit. That is why they are so safe. It seems that ethylene is the preferred gas in America, while acetylene is preferred in Europe. The latter is much less expensive. There are other factors that make these gases safer. Postanesthetic bronchopneumonia raises the ether or chloroform mortality rate to from 3 to 5 per thousand. The explosion mortality rate of ethylene can be reduced to 1 per hundred thousand, while postanesthesia complications are absent. An experimentally demonstrable therapeutic potentiation occurs with barbiturate basis narcotics and the inhalation anesthetics, as well as between barbiturates and the local anesthetics. The author discusses Cloetta's demonstration of a "sleep steering center," located in the base of the brain and in front of the aqueduct of Sylvius, which induces sleep under the influence of calcium excess and wakefulness under the action of potassium excess, the calcium lessening cell permeability while potassium increases it. A sensitization of the center to the calcium action is required for the production of sleep, and this occurs through modification of the center to favor calcium accumulation, which is affected by fatigue products as well as by hypnotics. These examples might suffice to give some indication of the wealth of new material contained in this supplement.

**A Text-Book of Histology Arranged upon an Embryological Basis.** By J. Lewis Bremer, M.D., Hersey Professor of Anatomy, Harvard University. Fifth edition of "Lewis and Stöhr." Fnbrikoid. Price, \$6.50. Pp. 580, with 455 illustrations. Philadelphia: P. Blakiston's Son & Co., Inc., 1936.

Much of the modern histologic investigation consists of attempts to correlate cellular structure and function. The vast amount of work in the fields of endocrinology and of secretions of glands in general, the influence of recent experimental embryology, and the introduction of new experimental methods in histology have all served to move histology from the static, purely descriptive position which it occupied for many years to a place among the most active and progressive of the medical sciences. This change in the scope of histology is reflected in the present extensive revision of this well known book. Although it still presents histology primarily from the embryologic point of view, this edition differs from previous ones in containing much physiologic information. The most extensive changes and additions are in the descriptions of the endocrine glands, the kidneys, the teeth, and blood formation. There are many new illustrations. The photomicrographs of dental structure are particularly demonstrative. Controversial matter has been presented in such a fashion that the opposing views are readily grasped by the student. Perhaps the main unfavorable criticism which might be directed toward it is that it is slightly oversimplified; and oversimplification, of necessity, often leads to slight inaccuracies. Of this the author was obviously aware, for he has sought to overcome this deficiency by the incorporation of many new references, which were selected to a large extent on the basis of availability to American medical students. As the author states in the preface, "even slight familiarity with the literature will disclose the active vitality of modern anatomical science." With this revision Professor Bremer has succeeded in making his book a clear presentation of modern histology for medical students.

**Investigations on Respiratory Dust Disease in Operatives in the Cotton Industry.** By C. Prusnitz. Medical Research Council, Special Report Series. No. 212. Paper. Price, 2s. 6d. Pp. 73, with 26 illustrations. London: His Majesty's Stationery Office, 1936.

A few decades ago the terms "byssinosis" and "byssophtthisis" found their way with fair frequency into discussions of dusty lung diseases. The concept then was that cotton dusts produce in workers a lung disease analogous to silicosis. Greater experience has proved that little is shared in common by cotton and silica dusts. Nevertheless, morbidity statistics continually present an abnormal incidence of pulmonary diseases among cotton workers. Tuberculosis, bronchitis and asthma stigmatize these mill workers. In the United States a satisfying but perhaps erroneous explanation was found in the cotton worker's low standards of living, his poor housing, low wages, fatigue producing work, and high humidity in work rooms. In England, physicians and hygienists have persisted in the belief that cotton dust itself or some component is the direct source of

"mill fever" and remotely the source of more severe disorders. At one time histamine, a constituent of cotton dust, was marked with suspicion as the cause of mill workers' lung diseases. In fact, histamine may play some part but is not the exclusive agent responsible. This English book provides an admirable presentation of the entire problem of respiratory disease among cotton operatives. The chief new material deals with extensive experiments on man and animals applying various extractives of cotton. In the protein fraction there has been found a substance believed to be the specific cause of mill intoxications. This substance acts chiefly as a sensitizing agent but in addition appears to possess direct irritant properties so that, even in the absence of allergic states, damage may arise. Injury from cotton dust is reported as not limited to the respiratory tract. Marked changes are reported as occurring in the adrenals. The contents of this small book are presented in four major divisions, on the chemistry and physics of cotton dust, experimental investigations, clinical and physiologic observations and diagnosis, treatment and prevention. In the last section it is recorded that desensitization is not effective at this time and that no treatment is of specific worth. Stress is placed on the prevention of these diseases through the elimination of dust in the cotton mill atmosphere. Since American cotton proved to contain just as much toxic material as batches from other portions of the world, no reason prompts the belief that American operatives may be free from this occupational disorder. This book should become the possession of physicians working in the cotton textile areas of this country, as well as industrial physicians and hygienists everywhere.

**Gynecology for Nurses.** By Harry Sturgeon Crossen, M.D., Gynecologist to Barnes Hospital, St. Louis Maternity Hospital, and St. Luke's Hospital, and Robert James Crossen, M.D., Instructor in Clinical Gynecology and Obstetrics, Washington University School of Medicine. Second edition. Cloth. Price, \$2.50. Pp. 316, with 365 illustrations. St. Louis: C. V. Mosby Company, 1936.

The excellent features of the first edition, namely, good illustrations, careful proportion of subject matter, simple exposition, and minute attention to details, are embodied in the second edition of this manual, which has now been brought down to date by the inclusion of sections on endocrinology and references to newer therapeutic measures, such as the Elliott treatment. The aim of the work is to provide the student nurse, the supervising nurse, the operating room nurse or the office nurse with sufficient knowledge of gynecology for the proper understanding of her work and, further, to provide her with detailed instruction in gynecologic nursing technic. This design has been admirably fulfilled. The personal views of the authors, which are of especial interest to the experienced surgeon or nurse, may limit somewhat the general acceptance of the volume as a textbook, since every hospital is inclined to teach its student nurses its own technic. Nevertheless, supervisors of nurses and private duty nurses will find the book of great reference value. Those accustomed to the authors' style will not think the new volume poorly written.

**Alimentación de niños. Métodos de México.** Por el Dr. Juan M. González. Cloth. Pp. 718, with illustrations. Mexico, D. F.: The Author, 1936.

This book, in Spanish, is on the methods used in feeding Mexican infants. The first 170 pages deals with the weight and body measurements of Mexican children, breast feeding and the feeding of premature infants. The average Mexican child weighs 3,300 Gm. at birth and is 51 cm. long. It weighs 7,200 Gm. at 6 months and 9,350 Gm. at 1 year. It can therefore be seen that, whatever their type of feeding may be, these infants quite compare in body build with infants in this country. Breast feeding is advocated, and considerable space is given to reasons and to technic. The author prefers a three hour interval, but only five feedings in twenty-four hours. Much attention is given to manual expression and the Abt pump. His regimen for premature infants is quite like ours, and he advocates breast milk for their feeding.

The second part of the book deals with artificial foods. Cow's milk is preferred. The Holando-Mexican breed of cattle produces the best milk for infant feeding, as the fat globule is almost the same size as human milk. Milk should be pasteurized or home boiled. Next in preference are acid milks or banana milk (made by emulsifying a ripe banana in 0.5 liter of milk). Vitamin C is furnished in fruits, and sunshine gives

vitamin D. The other vitamins the author states are furnished in the ordinary diet. The fortunate Mexican mother therefore does not have to listen to vitamin propaganda.

Probably the most interesting section of the book is that dealing with artificial feeding. The artificially fed baby receives seven milk feedings a day until 3 months of age and six feedings a day to 10 months. Cooked apple is added at 7 months and banana and other fruits and vegetables at from 7 to 10 months. At 1 year the Mexican baby has four milk feedings, fruit, vegetable and egg yolk. Bread is added at 18 months, and at 2 years a soup made of meat and egg. The preschool child has four meals a day of milk, soup, egg, meat, bread, vegetable and corn meal pancake. These meals are at 8, 12, 4 and 7 o'clock.

The final part discusses digestive disturbances. Finkelstein's classification is used, and the treatment is quite like ours. Chapters are devoted to intravenous dextrose therapy and blood transfusions.

The book is well written and intensely interesting. The physician who wishes to learn of the feeding methods used in other countries will profit by reading this. It is so beautifully done and so profusely illustrated that the fact that it is written in Spanish should be no handicap.

**Principles and Practice of Recreational Therapy for the Mentally Ill.** By John Elsie Davis, B.A., M.A., Senior Physical Director, Veterans Administration Facility, Perry Point, Maryland. In collaboration with Dr. William Rush Dunton, Jr., Instructor in Psychiatry, The Johns Hopkins University. Cloth. Price, \$3. Pp. 206. New York: A. S. Barnes & Company, Incorporated, 1936.

Organized recreation in hospitals for mental disease, used as a form of occupational therapy, is of comparatively recent development. The book at hand appears to be the first of its type and as such is of great interest to all physicians who care for patients with psychoses in hospitals. After an introductory chapter listing the various types of disease usually found in such hospitals, details of recreational activities are given which appear to the author to be best suited for patients with such diseases as dementia praecox, encephalitis and paranoia. It is too early to evaluate the effect of such recreational exercises and this the author does not attempt to do. In the final chapter he outlines the aims and objectives of his work, which was largely accomplished in a hospital under the Veterans' Administration. Only when other hospitals have adopted similar programs can the value of this work be estimated. This book, extremely well written, will serve as a basis for the instigation of similar programs in other hospitals.

**Reports on Chronic Rheumatic Diseases. Being the Annual Report of the British Committee on Chronic Rheumatic Diseases Appointed by the Royal College of Physicians.** Edited by C. W. Buckley, M.D., F.R.C.P. Number Two. Cloth. Price, \$3.50; 10s. 6d. Pp. 140. New York: Macmillan Company; London: H. K. Lewis & Co., Ltd., 1936.

While the title of this book might lead one to believe that it represents the prevailing opinion of the British Committee on Chronic Rheumatic Diseases, the editor frankly states that "it is not to be assumed that the views expressed . . . are necessarily the views of the British Committee. Their object is to present accounts of clinical and laboratory observation and research which they believe to be of real value, but beyond this, they do not desire to hamper contributors in the expression of their opinions." The volume consists of ten articles by physicians whose names have been identified for a long time with the study of the rheumatism problem. One of the articles giving an excellent cross section of the American concept of the problem was written by Dr. Philip S. Hench of Rochester, Minn. The other nine articles were written by British physicians. The book should appeal particularly to the rapidly increasing group of physicians who are interested in the subject of arthritis. While no specific advance in the knowledge of the disease or its treatment can be gained from reading the book, it contains a wealth of thought-provoking material which in time may be translated into definite progress. The liberal attitude of the committee toward tenable but unproved theories is to be commended and is in line with the thought with reference to arthritis recently expressed editorially in *THE JOURNAL*; namely, "The only advance has been in the tolerance of most writers for the views of others; this open-mindedness in a field in which nobody knows much is a necessary prerequisite to the acquirement of knowledge."

**Orthopedic Surgery.** By Walter Mercer, M.B., Ch.B., F.R.C.S., Assistant Surgeon, Royal Infirmary, Edinburgh. With a foreword by John Fraser, M.C., M.D., Ch.M., Regius Professor of Clinical Surgery in the University of Edinburgh. Second edition. Cloth. Price, \$10. Pp. 906, with 408 illustrations. Baltimore: William Wood & Company, 1936.

The first edition was reviewed in *THE JOURNAL* Sept. 2, 1933. It was pointed out that the book was an outgrowth of the author's lectures in clinics given under the direction of Professor Fraser and that it reflected the general surgical rather than the orthopedic point of view. In the present edition the author claims to have benefited by the criticisms with which his first edition was received. He has added the more important developments in orthopedic surgery that have appeared since 1933. Several of the sections have been rewritten, including those on pneumococcal arthritis, gonococcal arthritis, hemophilic arthritis, hysterical joints and the muscular dystrophies. There are two new chapters on circulatory disturbances of the extremities and on manipulative surgery. All these additions resulted in 200 additional pages and thirty-seven additional illustrations. Most of the illustrations in the present edition are instructive. However, they would be more instructive if the legends were more explanatory and if there were markings on the illustrations themselves to indicate to students just where the pathologic changes lie.

**Asthma: Aerodynamik und Therapie.** Von Dr. med. Otto Busing. Boards. Price, 3.50 Swiss francs; 2.80 marks. Pp. 68, with 10 illustrations. Berne: Medizinischer Verlag Hans Huber, 1936.

The author expounds his theory of distorted air currents created in the nasal passages as the important etiologic factor in bronchial asthma. He states that normally the middle meatus is the passage through which the main current of air reaches the trachea. The observations have been made by means of (1) direct rhinoscopy with tobacco smoke as a means of visualizing the air currents, (2) animal experiments, (3) the use of models of the human nose, and (4) technical apparatus and calculations. During the asthmatic attack the inferior meatus becomes the main passageway for the air currents, the latter becoming distorted and causing the asthmatic attack. The most important factor in the production of these distorted currents is the inferior turbinate, which becomes bulbous at both ends and constricted in the center. The author's therapy consists of flushing a warm solution of sodium, potassium and calcium salts in neutral solution against the inferior turbinate, the use of gargles, the internal use of calcium salts and expectorants. He advises against the local use of ephedrine and epinephrine. He limits his surgical procedures to the removal of redundant mucosa occasionally found posteriorly on the inferior turbinate, the careful removal of polyps, occasionally submucous needling of the inferior turbinate, and occasionally a submucous septum resection. The cases presented are few and hastily sketched. He takes much for granted and in places his ideas are quite fantastic.

**Die Bekämpfung der eklampischen Schwangerschaftserkrankungen.** Von Dozent Dr. med. Heinrich Sledentopf, Oberarzt der Universitäts-Frauenklinik zu Leipzig. Paper. Price, 4.50 marks. Pp. 86. Leipzig: Johann Ambrosius Barth, 1936.

In this small monograph the author reviews briefly the present treatment of eclampsia. In that the cause of this obstetric complication is not known, he evaluates the various therapeutic measures that have been used in the large clinics of the world. The prophylactic treatment of eclampsia is probably the most important measure in the therapy of the disease. To this end, good antepartum care is necessary. He thus makes a plea for the widespread use of antepartum care in all obstetric patients.

The author concludes from statistics from his own clinic in Leipzig, as well as from many other representative clinics, that certain principles stand out in the treatment of eclampsia. The disease should be treated in the preeclamptic stage by rest, sedatives and concentrated dextrose solutions and, if the condition fails to improve, the termination of pregnancy is advocated. This can usually be done by the mechanical induction of labor, although cesarean section is occasionally advisable. In the convulsive stage, delivery from below is rarely indicated. Local anesthesia should be used. The residual damage following preeclampsia and eclampsia is properly emphasized. Future pregnancies may be complicated by abortion, stillbirth or abruptio placentae. These sequelae reduce the number of future

offspring. The possible decrease in the number of conceptions following toxemias is questionable and theoretical. The high fetal mortality in the toxemias of pregnancy is pointed out. Antepartum care and the general plan for the treatment of the toxemias of pregnancy presented in this book have been in use in most of the large American clinics for many years.

**Operative and Interpretive Radiodontia: A Textbook for Students and Practitioners of Dentistry.** By Walter S. Thompson, D.D.S., Associate Professor of Radiodontia, College of Dentistry, University of Southern California. Cloth. Price, \$7. Pp. 374, with 353 illustrations. Philadelphia: Lea & Febiger, 1936.

Intended essentially for dental students and dentists, this volume holds interest also for physicians, particularly roentgenologists. It presents a survey of the principles and practices of dental roentgenography, with particular attention to the mechanical or technical phases of this method. The introductory chapters on the history, the fundamental principles and the dental application of the x-rays are admirably suited to the readers for whom the book was written. The mechanics and technic of radiodontia are presented with exacting, at times redundant, detail. To the dental practitioner this, no doubt, is of great value. Unfortunately there is a corresponding lack of detail in the discussion of the interpretation of the roentgenograms. Only twenty-five pages is devoted to specific diagnosis, and this is presented largely by illustrations of typical roentgenograms of various disease conditions of the mouth and jaws. While the general principles of diagnosis are stressed, there is no effort to detail the points on which specific diagnoses are based or to present any real differential diagnosis. As an introduction to dental roentgenography and as a manual of technic the book is admirable, but it fails to provide an adequate treatment of interpretative radiodontia.

**Amino Acid and Ammonia Metabolism in Liver Diseases.** By Esben Kirk. Paper. Price, 10 Danish kroner. Pp. 147. Copenhagen: Levin & Munksgaard, 1936.

It is shown from the literature and new experiments that the liver is the exclusive site of urea formation and the chief site for the deamination of amino acids. But a small amount of liver tissue is adequate, so that in cirrhosis of the liver and feeding ammonia, although high blood ammonia values were observed in eighty-two cases, it does not indicate any inadequacy of the liver but may be due to an anastomosis between the portal vein and the vena cava. In acute hepatitis and obstructive jaundice and some other liver diseases there was no abnormal increase in blood ammonia on the feeding of ammonia. Folin's colorimetric method for amino nitrogen determination was shown to give very low values and therefore was discarded. After ingestion of 25 Gm. of aminoacetic acid, amino nitrogen was determined in the blood plasma by the Van Slyke method in twenty-two normal subjects, fifteen cases of acute hepatitis, thirteen of liver cirrhosis and eight of obstructive jaundice. Some variations were observed but were ascribed to retarded absorption of amino acids. In liver disease the fasting amino nitrogen values were found to be within the normal range. Similar results were found with relation to amino nitrogen excretion in the urine, where the determination was made by the modified formol titration. It is suggested that blood ammonia determinations are useful in the diagnosis of cirrhosis of the liver.

**Psychology of Sex: A Manual for Students.** By Havelock Ellis. Cloth. Price, \$3. Pp. 377. New York: Emerson Books, Inc., 1935.

The author of this volume is also the author of a seven-volume series called "Studies of the Psychology of Sex." His extensive work is more particularly suited to the use of physicians, psychologists, and those whose professional lives are greatly concerned with the problems considered. The present volume is more nearly a manual for the general student. It sets forth the view of the author that there is no sharp boundary line between normal and abnormal in sex matters. It provides a concise consideration of such topics as sexual deviations, homosexuality, marriage, the art of love, and the dynamic nature of the sex impulse. For the general reader the book is an adequate presentation of the Havelock Ellis views. It makes clear many subjects which have formerly been considered well concerned in mystery. There is an inefficient glossary and a fairly good index.

**Syndromes myo-parathyroïdiens simples ou associés.** (Myopathies scléreuses et scléro-hypertrophiques liées à des troubles parathyroïdiens.) Par André Percola. Paper. Pp. 88, with 10 illustrations. Paris: Librairie Le François, 1936.

The purpose of this monograph is to prove the relationship between parathyroid disturbances and atrophic myotonia. The author reports in detail seven clinical histories, with some laboratory data as a basis for his contention that these muscular dystrophies are secondary to parathyroid disturbances, supporting the thesis further by some sketchy quotations from the literature. The bibliography is composed of standard references, but some of the best work in this field has been omitted. While the book is interesting and informative in that it records some clinical observations, one is not impressed with the proofs offered. The work is more speculative than inquiring but still is interesting to both the investigator and the specialist. Some of the illustrations are good, others poor, owing to imperfect reproduction.

## Bureau of Legal Medicine and Legislation

### MEDICOLEGAL ABSTRACTS

**Malpractice: Statute of Limitations as Discriminatory Against Osteopaths and Chiropractors.**—In South Dakota, an action against "a physician, surgeon, dentist, hospital or sanitarium for malpractice, error, mistake or failure to cure, whether based on contract or tort" must be brought within two years. The plaintiff sued the defendant, a physician, for malpractice and the lower court held that the action was barred by the two year statute of limitations. The plaintiff appealed to the Supreme Court of South Dakota, contending that the statute was unconstitutional in that it placed physicians and the other named groups in a privileged class and was therefore discriminatory against osteopaths, optometrists, chiropractors, nurses and midwives.

If, said the Supreme Court, the statute does discriminate in favor of physicians and against chiropractors, osteopaths or the other classes referred to by the plaintiff, it is no concern of the plaintiff. He has not brought himself within any of the classes which he alleges are discriminated against and cannot, therefore, raise the question of discrimination against such classes. There was no contention that the statutory two-year period was unreasonable. Furthermore, the statute applies equally to any one having an action against those enumerated therein and the plaintiff was placed in the same position as any other person having a claim against those specified in the statute. The judgment for the defendant was consequently affirmed.—*Petersen v. Holif (S. D.)*, 266 N. W. 252.

**Workmen's Compensation Acts: Death from Diabetes Aggravated by Trauma.**—The worker had diabetes, which had been kept under control for over five years by diet and insulin. In the course of his employment, a truck ran over his right foot and leg, spraining the ankle and inflicting a cut of about 1½ inches in length and going to the bone. He continued to work that day and part of the next day but was unable to work thereafter. The lacerated wound on his leg became infected, the diabetic condition grew worse and twenty-five days after the accident the worker died of "acidosis due to diabetes." His widow, in proceedings under the Missouri workmen's compensation act, was awarded compensation and from a judgment of the circuit court, Jackson county, affirming that award, the employer appealed to the Kansas City court of appeals.

The employer contended that there was no causal connection between the worker's injury and his death. The court of appeals, however, did not agree with that contention. The evidence clearly showed, said the court, that the diabetic condition of the worker was under control prior to the industrial accident, that that control was disturbed because of the infection in the leg, and that it became impossible to reestablish it. As a consequence, the diabetic condition became aggravated and death resulted. Two physicians who attended the worker testified that they made strenuous efforts to reestablish the

"balance" in the sugar content of the worker's blood but were unable to do so because of the presence of the infection. Each of these physicians testified that the injury and the resulting infection directly contributed to his death. If, said the court, the industrial accident was a contributing factor to death, it must have been, to the extent it contributed, the cause of death, even if there were other contributing factors or causes. The fact that the worker had diabetes which contributed to his death constitutes no bar, the court said, to the widow's right to compensation, even though without diabetes the injury sustained by the accident would not have been fatal. As was said by the court in *Harder v. Thrift Construction Co. (Mo. App.)* 53 S. W. (2d) 34, at page 37:

Generally speaking, the rule is that the act [the workmen's compensation act] contemplates latent or dormant ailments; that the existence of a disease which does not impair the employee's ability to work will not prevent a recovery if the accidental injury accelerates or aggravates such disease to a degree of disability or of death; and that an actual aggravation of an existing infirmity caused by accident arising out of and in the course of the employment is compensable, even though the particular accident would have produced no such result in the case of a normal and healthy individual.

The court of appeals accordingly affirmed the judgment of the circuit court upholding the award of compensation.—*Tralle v. Chevrolet Motor Co. (Mo.)*, 92 S. W. (2d) 966.

**Accident Insurance: Right to Benefits as Affected by Refusal to Submit to Surgical Operation.**—The defendant insurance company promised to pay Sanders certain monthly benefits if he became totally and permanently disabled. Subsequently benefits were paid him when he became totally and permanently disabled because of "fistula and other ailments." Some time later his attending physician recommended that his teeth be extracted, that his tonsils be removed and that he "undergo a surgical operation for fistula." On Sanders' refusal to submit to the suggested procedures, the defendant insurance company declined to make further payments under the policy. He then instituted the present action and recovered judgment, the insurance company appealing to the Supreme Court of Arkansas, contending that Sanders' refusal to submit to the suggested operations relieved it of further liability.

A person is not required, said the Supreme Court, to undergo a major surgical operation against his will for the purpose of freeing another from consequent damages. Even a simple minor surgical operation may be compelled only where a reasonably prudent person would submit thereto. In determining what constitutes reasonable or unreasonable refusal to submit to surgical operations to correct total and permanent disability each case must, of necessity, rest on its peculiar facts and circumstances, and when a jury, as in the present case, has determined this issue on conflicting evidence, its finding is conclusive on appeal.

The Supreme Court accordingly affirmed the judgment in favor of Sanders.—*Actua Life Ins. Co. v. Sanders (Ark.)*, 93 S. W. (2d) 141.

### COMING MEETINGS

- American Academy of Orthopedic Surgeons, Cleveland, Jan. 11-13. Dr. Philip Lewin, 55 East Washington St., Chicago, Secretary.
- Eastern Section, American Laryngological, Rhinological and Otolological Society, Boston, Jan. 7. Dr. D. C. Jarvis, Quarry Bank Bldg., Barre, Vt., Chairman.
- Middle Section, American Laryngological, Rhinological and Otolological Society, Chicago, Jan. 11. Dr. Alfred Lewy, 25 East Washington St., Chicago, Chairman.
- Mid-Western Section, American Laryngological, Rhinological and Otolological Society, Chicago, Jan. 11. Dr. Frederick A. Figi, 436 Tenth Ave., S.W., Rochester, Minn., Chairman.
- Puerto Rico, Medical Association of, San Juan, Dec. 18-20. Dr. Dolores M. Pinero, Ave. Fernandez Juncos, Parada, 19, Santurce, Secretary.
- Society of American Bacteriologists, Indianapolis, Dec. 28-30. Dr. I. L. Baldwin, College of Agriculture, University of Wisconsin, Madison, Wis., Secretary.
- Society of Surgeons of New Jersey, Newark, Jan. 6. Dr. Walter B. Mount, 21 Plymouth St., Montclair, Secretary.
- Southern Section, American Laryngological, Rhinological and Otolological Society, Memphis, Tenn., Jan. 13. Dr. Charles D. Blassingame, Physicians and Surgeons Bldg., Memphis, Tenn., Chairman.
- Western Section, American Laryngological, Rhinological and Otolological Society, San Diego, Calif., Jan. 30-31. Dr. David R. Higbee, 3245 Fourth Ave., San Diego, Calif., Chairman.

## Current Medical Literature

### AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers in continental United States and Canada for a period of three days. Periodicals are available from 1926 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them. Titles marked with an asterisk (\*) are abstracted below.

**Pulmonary and Cardiac Factors in Lung Disorders.**—Oppenheimer and Hitzig studied fifty-four cases of bronchogenic (obstructive) emphysema and sixteen cases of bronchial asthma. The circulatory measurements employed were initial venous pressure, the rise of venous pressure during right upper abdominal quadrant compression, the arm-to-lung time (ether), the arm-to-tongue time (saccharin or sodium dehydrocholate) and the lung-to-tongue time (saccharin time minus ether time). Uncomplicated pulmonary insufficiency is usually attended by normal circulatory measurements. The presence of abnormal circulatory measurements indicates that pulmonary insufficiency is complicated by myocardial failure. Incipient isolated right heart failure is characterized by the presence of a normal initial venous pressure, and a varying rise in this pressure during right upper quadrant compression. The arm-to-lung time may or may not be prolonged, and the lung-to-tongue time is normal. Frank isolated right heart failure is characterized by high initial venous pressure, considerable rise on right upper quadrant compression, prolongation of the arm-to-lung time and a relatively normal lung-to-tongue time. Left heart failure is characterized by normal initial venous pressure with or without a rise on right upper quadrant compression, a normal or slightly prolonged arm-to-lung time, and a considerably prolonged lung-to-tongue time. Universal heart failure is characterized by high initial venous pressure, with a considerable rise in right upper quadrant compression and prolongation of the arm-to-lung time and lung-to-tongue time. Bronchial asthma with a few exceptions is characterized by normal initial venous pressure, absence of a rise of right upper quadrant pressure, and normal or fast normal circulation times. Cardiac asthma is differentiated from bronchial asthma by the presence of abnormal circulatory measurements. That incipient right heart failure also frequently accompanies left ventricular failure may be demonstrated by the method of compressing the right upper quadrant of the abdomen and observing the presence of a rise in the normal initial venous pressure level. In chronic bronchopulmonary disease there is apparently no parallelism between the severity of the clinical symptoms and the slowing of the pulmonary blood flow.

#### Relation of Tachycardia to Cardiac Insufficiency.

Luten asserts that the various elements of the circulation are subject to reflex variation. By reciprocal adjustments, balance tends to be maintained despite disorder in one component. Primary impairment of the peripheral circulation or of cardiac output produces reflex acceleration of the sinus heart rate. Compensatory tachycardia is physiologic, not harmful. Its primary abatement is not a proper therapeutic objective. Improvement is followed by reverse slowing. Conversely, primary acceleration of rate tends to induce compensatory adjustment in blood pressure and in systolic discharge. With sinus rates nearly as high as 200, the circulation remains adequate. In auricular fibrillation the ventricular rate appears to depend largely on the state of the ventricular muscle. This arrhythmia frequently occurs in congestive heart failure. Under such circumstances reduction in rate follows improvement in the muscle, from digitalis or from other cause. In cases of fibrillation without heart failure the muscular effect of digitalis is not beneficial; in such instances, administration of the drug is not followed by slowing. In auricular fibrillation, as in normal rhythm, abatement of tachycardia appears not to be the cause of improvement but to be the result of it.

**Sudden Arterial Occlusion in Thrombo-Angiitis Obliterans.**—Kvale and Allen reviewed the records of 255 carefully studied cases of thrombo-angiitis obliterans. Arterial thrombosis, as a primary clinical manifestation of thrombo-angiitis obliterans, occurred suddenly in eleven of their 255 cases. None of the patients were under their observation at the time occlusion occurred. Amputation was eventually necessary in two cases. Arterial thrombosis may occur suddenly in the course of well developed thrombo-angiitis obliterans and did in fifteen. Only two of the fifteen patients were under the authors' observation at the time occlusion occurred. Amputation of a leg was subsequently necessary in ten cases. Treatment, which should be begun promptly, consists of relief of pain, avoidance of burning the limb and the relief of arterial spasm, or the induction of vasodilatation, by means of drugs, intermittent negative and positive pressure, artificially induced fever or anesthesia.

**Life Expectancy in Malignant Disease.**—Nathanson and Welch calculated the life expectancy in 1,565 treated cases of carcinoma of the breast observed in the Huntington Memorial and Pondville hospitals. The age and sex incidence in 2,190

cases of cancer of the breast seen in the same institutions have been determined. The average length of life from onset of the disease is 3.5 years in patients treated in the years 1912 to 1932, compared with 2.5 years in those untreated. There is no absolute proof from these data that the treatment of carcinoma of the breast has increased the life expectancy significantly in the years 1923 to 1932 compared with that of the years 1912 to 1922. The Huntington group shows a definite improvement in the second decade, but this is probably due to a more favorable group of cases. The median length of life in the age group less than 40 is about three years, from 40 to 60 about three and a half years, and about four years thereafter. Cancer of the breast in the hospital cases is more malignant in the young and less so in the old. Men seem to have a slightly better life expectancy than women, but the number of male cases is too small for positive conclusions. Susceptibility to cancer of the breast increases steadily with age.

**Splenectomy in Treatment of Subacute Bacterial Endocarditis.**—Riesman and his associates find that splenectomy for subacute bacterial endocarditis is well borne even in far advanced cases. It has not so far been followed by a permanent sterilization of the blood stream in cases in which blood stream infection has existed. Nevertheless, life is unquestionably prolonged and made more comfortable. The physical and psychic improvement is most impressive. Even if the infectious process should continue in the heart, and it is possible that even this might be favorably affected, it seems that the general condition of the patient is improved. Perhaps if the operation should be done earlier in patients with palpable spleens and hearts not too badly damaged, the results might be better. As death seems to be due in the majority of cases to embolism, the prevention of this complication should be taken into consideration. Treatment should not rest with splenectomy. Repeated small transfusions should be continued and bacteriophage therapy tried. Splenectomy may prove to be a method of dealing with intractable forms of sepsis without discoverable focus in which splenomegaly is a prominent feature. This

group, in which subacute bacterial endocarditis may be suspected but is unproved, at present promises the best results from the operation.

**Blood Phosphatase and the Diagnosis of Jaundice.**—Clinical data are presented by Rothman and the Meranzes to substantiate Roberts' original assertion concerning the clinical usefulness of phosphatase determinations in the differential diagnosis of jaundice. Attention is called to a number of instances in which the phosphatase values were greater than 10 units. They cannot, however, entirely agree with Roberts when he states that it is not necessary to know the concomitant serum bilirubin values in order to interpret the phosphatase readings. A comparison of the relative increase in the values of phosphatase and serum bilirubin above their respective normals gives additional aid in diagnosis and, in particular, makes possible a correct interpretation of those borderline values of 10 units or slightly above. The basis for this belief lies in the observation that in obstructive jaundice the rise in the phosphatase and serum bilirubin tends to run parallel until the limits of the phosphatase values are reached. In non-obstructive cases, on the other hand, in spite of the progressive increase in serum bilirubin, the phosphatase values rarely rise above 10 units and no parallelism is noted. Phosphatase determinations should be considered as representing a composite of effects, the dominant pathologic state exerting the greater influence on its value. The test can serve as a means of differentiating between the two classes of jaundice only in the absence of other conditions affecting phosphatase. The specific etiology must at present be inferred from other studies. In its ability to help differentiate between an obstructive and a nonobstructive jaundice, however, the phosphatase determination appears to be superior to other available tests, the galactose tolerance test in particular, when the latter is used to detect acute parenchymal liver disease. Too much reliance must not be placed on a single phosphatase determination. If, for example, a first estimation of phosphatase were to be made early in the onset of obstructive jaundice, as the jaundice is developing, it is conceivable that the phosphatase value, rising slowly in proportion, may not as yet have reached diagnostic heights. The low phosphatase value obtained under such conditions may be misleading.

**Anemia in Pregnancy.**—Adair and his collaborators illustrate the importance of the chemical determination of hemoglobin in pregnancy by stating that the test indicates that 63 per cent of pregnant women are anemic according to nonpregnant standards. Their data indicate that the concentration of hemoglobin, the cell volume and the erythrocyte count are definitely decreased during pregnancy and that the normal standards for the nonpregnant differ from those of the pregnant women. Statistically the minimal figures in normal pregnancy should be 10.16 for hemoglobin, 33.11 for cell volume and 3.36 for the erythrocyte count. The physiologic decrease and increase in

hemoglobin, cell volume and erythrocytes during pregnancy have not been evaluated properly. The fact that the hemoglobin concentration can increase 2, 3 or even 6 Gm. within four weeks without treatment at once casts doubt on any reports which state that improvement occurred during pregnancy when iron salts were administered. It is the authors' belief that the hemoglobin concentration of the cord blood is usually normal even though the mother has an anemia, but in a number of instances the hemoglobin concentration has been definitely below normal. This is especially important in view of the fact that milk contains little iron and, if the baby begins life with a low concentration of hemoglobin, anemia is quite likely to develop. This is still more important in premature infants, as they are born without the storage of iron in the liver which exists in the term baby. Severe anemia predisposes to premature delivery. Transfusion of blood, if properly supervised and if adequate amounts are given, has always been efficacious in raising the hemoglobin concentration and relieving all symptoms and signs of anemia. There was no case of premature labor. If the cause of the anemia occurring in pregnancy was merely a lack of iron in the diet, patients who receive iron should all show rapid improvement when adequate amounts of iron are added. The fact that a considerable number of patients show no improvement indicates that some other substance is lacking or that the iron is not being absorbed or that, if absorbed, it is not being utilized. The prevention of anemia of pregnancy is easier than the cure. An adequate diet, with proper hygiene, is the best prophylaxis.

**Estrogenic Substances in Blood of Women.**—Fluhmann examined 401 specimens of blood from eighty-four women and fifteen prepubertal girls. The blood of five of seven normal girls between the ages of 8 and 10 years gave positive reactions for estrogenic substance, whereas the tests were negative in seven of eight girls from 4 to 7 years of age. In twenty-two of twenty-five patients it was found that during the course of the menstrual cycle there was an increase in the concentration of estrogenic substance in the blood, which occurred during the midinterval and seemed to be associated with ovulation. A secondary rise just before or at the onset of menstruation was observed in seven instances. No characteristic variations were observed in four patients with anovulatory cycles. Of sixteen cases of menorrhagia, polymenorrhea or uterine hemorrhage due to hyperplasia of the endometrium, a rise in the concentration of the blood estrogenic substance was observed in ten at the onset of the bleeding. In patients with amenorrhea there was a cyclic rise and fall in the amount of estrogenic substance, a constant moderate amount of estrogenic substance was present or there was a persistent absence of demonstrable estrogenic substance. Estrogenic substances were found in the blood of women following castration and in the postclimacteric period. The presence of estrogenic substance in the blood was demonstrated in association with increased amounts of gonadotropic substance.

**Relation of Endometrial Hyperplasia to Adenocarcinoma of Uterus.**—Novak, with the assistance of Yui, reviewed the records of 12,813 cases that have been examined in his laboratory during a period of eleven years. They found 804 instances of endometrial hyperplasia and 104 of corporeal adenocarcinoma that suggested a relationship of some sort between the two conditions. While in the majority of cases hyperplasia is a frankly benign lesion, a small minority (fourteen of the 804) present evidences of marked proliferative tendencies, which may even simulate cancer. Atypical gland proliferations simulating adenocarcinoma are especially frequent in the polyps so often seen with hyperplasia. Hyperplasia is not rare in women long after the menopause (forty cases). The occasional occurrence of hyperplasia with bleeding in elderly women lessens the probability of granulosa-cell carcinoma of the ovary, unless an ovarian tumor can actually be palpated. In the study of the 104 cases of adenocarcinoma, the most impressive result was the demonstration of a coexisting hyperplasia and adenocarcinoma in twenty-five of the cases in which some of the noncancerous endometrium was available for study. Since seventy-eight of ninety-two adenocarcinoma patients were past the menopausal age, this suggests that a postmenopausal hyperplasia, or the endocrine dysfunction responsible for it, must strongly predispose to the development

of adenocarcinoma. Since a persistence and relative excess of estrogenic substance is accepted as the cause of hyperplasia, it would seem that it is this endocrine factor which must be suspected as the one predisposing to cancer genesis. The author emphasizes not only that the ordinary hyperplasia of the reproductive period is frankly benign from the histologic standpoint but also that it has no apparent predisposing influence in the causation of adenocarcinoma during menstrual life. It would seem from his studies that it is the postmenopausal persistence of hyperplasia which is in some way bound up with the occurrence of the common postmenopausal type of adenocarcinoma. In his cases of coexisting hyperplasia and adenocarcinoma, he has been able to show a definite transition of the benign to a borderline and then to an undoubtedly malignant pattern in some cases, so that in the endometrium at least it would seem that one is dealing with histologic intergrades between benign and malignant lesions. Whether abolition of ovarian function by x-rays or radium in the treatment of functional bleeding of the menopause would be of any practical value is questionable, since it seems quite certain that other sources of estrogenic substance than the ovary must be reckoned with. In the cervix uteri, corpus uteri and breasts one has to deal with the possible rôle of ovarian hormones. This seems significant in view of the growing opinion that the carcinogenic possibilities of estrogenic substances are most to be reckoned with in those organs in the growth and activities of which the estrogenic principle normally plays an important part.

\*Massive Doses of Vitamin D in Treatment of Proliferative Arthritis. B. L. Wyatt, R. A. Hicks and H. E. Thompson, Tucson, Ariz.—p. 534.

**Massive Doses of Vitamin D in Treatment of Proliferative Arthritis.**—Wyatt and his associates selected forty patients having chronic infectious or proliferative arthritis for treatment by massive doses of vitamin D. These patients had been under observation for at least six months and it was possible thereby to contrast their progress before and after the administration of large doses of vitamin D. There was no special selection of patients other than that any patient was eliminated whose general condition was such that a severe reaction might be disastrous. Later it became evident that the presence of a very sensitive colon contraindicated the use of the vitamin in large quantities. In general it was found that the type of arthritic patient for whom vaccine is indicated was decidedly not the type in which to use massive doses of vitamin D. After a baseline in degree of progress for six months was established, massive daily doses of vitamin D (not more than 300,000 units, but usually 200,000 units) with supplementary medication (vitamin B and calcium) were instituted and similar studies of the patient were continued. The additional treatment of these patients consisted of adequate rest, physical therapy, heliotherapy, dietotherapy, treatment or early removal of foci, blood transfusions, orthopedic measures and intravenous bacterial antigen. There were individual variations. The percentage of clinical improvement noted was considered definite and clear cut in 20 per cent; i. e., in eight patients a definite progressive increase in appetite, weight, general feeling of strength and a decrease in joint swelling, pain and stiffness were evident. Similarly, in eight patients it was necessary to abandon the treatment entirely, owing to unfavorable reactions. The remaining twenty-four patients showed no definite benefits that could be attributed to vitamin D therapy. The morphologic blood picture did not alter in these patients more rapidly or more distinctly in general than it does in other patients

treated without vitamin D. Calcium and phosphorus determinations exhibited only minimal changes, the average increase in calcium content of the serum being from 0.75 to 0.95 mg. All determinations were within normal limits. There was no significant change in the calcium phosphorus ratio noted.

### Archives of Neurology and Psychiatry Chicago

36: 675-916 (Oct.) 1936

- Electrical Activity of the Cat's Brain. R. W. Gerard, W. H. Marshall and L. J. Saul, Chicago.—p. 675.

**Pick's Disease.**—Ferraro and Jervis conclude that in Pick's disease neuronal changes consist primarily of cellular atrophy extending to the whole cortex, with accentuation in the frontal and temporal lobes. The cortical senile atrophy may at times be most evident in the third layer, as is observed also in Pick's disease. Histopathologic details common to senility and to Pick's atrophy add further evidence to the similarity, among which are the frequency of pigmentary surcharge and fatty degeneration of the nerve cells, the presence of numerous corpora amylacea and torpedos, and the large amount of iron. The formation of cellular argentophilic inclusions may be due to a physicochemical process leading to the formation of argentophilic substance, which is commonly observed in association with senility. Senile plaques were not observed in the authors' two cases. However, the significance of these formations as pathognomonic of senile processes is still uncertain. In their cases, evidence of histopathologic changes representing tissue response to vascular involvement was observed. In striking contrast with these tissue changes, however, there were noted only slight alterations in the blood vessels, consisting mainly of fibrosis of a few capillaries and occasionally of endothelial proliferation. Similar contrasts are frequent in the general pathologic changes of arteriosclerosis. In Pick's disease, vascular spasm can explain the circumscribed zones of gross cortical atrophy as a result of repeated local vasospasms. Whether angiospasm may more easily affect predisposed tissue the authors are not prepared to say, though in their material they encountered changes comparable to those associated with normal and pathologic senility. The angiospasm might be produced by disturbance of the colloidal equilibrium or it may also be due to metabolic toxic factors of undetermined origin which act through the mechanisms of vasospasm or independently of it.

**Studies in Disseminated Alternative Arteriolitis.**—Bender presents two cases of disseminated alternative arteriolitis in which the typical vascular lesions were evinced in the brain as well as in other organs of the body, although endocarditis was not present. The two cases are instances of apparent infection, one associated with a pulmonary process and the other with an abortion, in which lesions of the heart valves and walls were not detected but in which the productive arteriolitis was present in the myocardium and in all internal organs, including the brain. The cerebral lesions were like those in other organs of the body and were characterized by endothelial proliferation, swelling, necrosis and obliteration of the lumen. This endothelial hypertrophy occurred especially as a knotlike process at the point at which the arterioles break into the capillary network. It had a characteristic localization in the central nervous system in the larger groups of nerve cells. The vascular lesions were associated with secondary loss or paling of the nerve cells and proliferation of the astrocytic cells and with typical neurologic and psychic disturbances related to the failure in function of the cerebral and cerebellar centers and those of the brain stem. The lesions and the secondary organic failure were progressive; in one case death was due apparently to cerebral failure and in the other to cardiovascular, renal and hepatic failure, with associated cerebral signs. The concept of this disease entity has evolved from that of acute bacterial endocarditis, in which an infectious agent produces a productive and destructive lesion of the whole inner lining of the cardiovascular system, with typical vegetative endocarditis in the more acute forms.

 Transparent Exophthalmometer. W. H. Luedde, St. Louis.—p. 681.

**Cataract Extraction Through a Vertical Conjunctival Slit.**—Moehle states that with his method of extracting the lens the anatomic conjunctival supply of blood to the region of the corneal section is retained, because the incision is made parallel to the course of the vessels, thus assuring maximal nutrition and avoiding unnecessary hemorrhage. The method also facilitates the making of the corneal section with a keratome, with subsequent enlargement of the section with scissors subconjunctivally. The vertical slit renders the iris and capsule accessible and does not interfere with the delivery of the lens. No conjunctival suture is required, since the undermined conjunctiva immediately lies smooth and flat, with the edges of the incised wound in close approximation. However, if desired, a suture may be inserted, closing the conjunctival incision.

**Choroidal Chorionepithelioma Secondary to Teratoma of Testicle.**—MacDonald saw a choroidal chorionepithelioma in a young man who complained of a painless mass in the scrotum. Marked endocrine disturbance was present, as he showed some of the secondary manifestations of pregnancy, linea nigra and female distribution of pubic hair, hypertrophy of the breasts and secretion in the acini. Following removal of the eye owing to the rapid growth of the tumor, the clinical diagnosis was made and was later confirmed at necropsy. The mixed tumor of the testicle was a true teratoma involving all three primitive layers. All the metastases were of the chorionepithelioma type and were widespread. The pituitary gland showed marked changes, and the Aschheim-Zondek test for urine was positive.

**Calcific Sclerosis of Aortic Valve (Mönckeberg Type).**—Sohval and Gross discuss the changes that they found in eighteen hearts with so-called Mönckeberg's calcific sclerosis of the aortic valve, in nineteen hearts with a grossly poly-

valvular extinct rheumatic process and in thirteen hearts with a grossly monovalvular extinct rheumatic process. Essentially different gross and microscopic features were revealed in the Mönckeberg and rheumatic valvular lesions. The heart with the uncomplicated Mönckeberg process shows practically none of the stigmas of extinct rheumatic fever and no other evidence which would indicate that the process is secondary to inflammatory changes. The possible mechanisms concerned in the development of the essential Mönckeberg process appear to be purely and primarily degenerative, its occurrence and extent depending in all probability on individual predisposition to collagen involution and lipid and calcium deposition. The lesions of three hearts with submarginal aortic commissural bridging of noninflammatory nature suggest that stress and strain in the aortic valve may serve as additional factors predisposing to degenerative processes. In certain persons in whom there exists a predisposition toward the deposition of lipid and calcium, inflammatory lesions with subsequent deformity of the aortic valve may impose sufficient strain on the valve to initiate the Mönckeberg process.

**Hemorrhage into Leaflets of Atrioventricular Valves.**—Clark and Berger observed hemorrhagic extravasation into noninflamed atrioventricular valvular leaflets at necropsy in four persons at Bellevue Hospital. In one, ecchymoses of the leaflets of the mitral and tricuspid valves accompanied similar extravasations beneath the mural endocardium. In the other three the strict limitation of the endocardial ecchymoses to the leaflets of the tricuspid valve and the coexistence of embolism of the pulmonary artery suggested a relationship between the hemorrhagic extravasations and the embolism. Though in all four cases some of the valvular ecchymoses involved the vascularized annulus and might have been due to rupture of those vessels, other hemorrhages were localized in the distal nonvascularized portions of the leaflets. The source of the red cells in the latter portions remains obscure. Though it is possible that cells from ruptured vessels at the annuli infiltrated the distal portions of the leaflets, no evidence of this was obtained even in serial microscopic sections. In view of the common persistence of vessels in the leaflets of the tricuspid and mitral valves, the possibility exists that the blood cells were derived from ruptured vessels which evaded detection. Penetration by cells from the chamber of the heart through disruption of the lining of the leaflets is impossible to exclude, although the authors could not establish it by microscopic examination. The limitation of the hemorrhages to the leaflets of the tricuspid valve in the three cases of pulmonary embolism reported here, as well as in the two described by Geipel, supports the belief that the two phenomena are related. Whether this is due to trauma to the leaflet by the embolus during its passage through the tricuspid orifice or as the result of an abrupt rise in intraventricular tension cannot be determined.

\*Local Heat Treatment in Ozena: Preliminary Report. C. K. Gale, New York.—p. 646.

**Local Heat Treatment in Ozena.**—Gale's method for the treatment of ozena consists of the direct application of heat to a large surface of the nasal mucous membrane for prolonged periods. Into the right nasal fossa a rubber applicator of special design and shape is inserted, which has been filled with barium for roentgenographic purpose. It extends the entire length of the inferior meatus back to the posterior nasopharynx and upward beyond the level of the middle turbinate. On inflation

it establishes contact with both the medial and lateral walls of the nose. If instead of barium the applicator is filled with a heated solution from an Elliott apparatus, a heat effect by direct contact over the entire area will be obtained. In the clinical application, suction is first applied which collapses the applicator by vacuum action and facilitates complete filling of the applicator with a solution only. The applicator is made of very thin but strong rubber and, when inserted into the nose, has the appearance and thinness of a jack knife blade. It has no shape but conforms by its ballooning action to the space in which it is confined. The ballooning out of the applicator establishes contact in the areas of the eustachian tube, sphenoid sinus and posterior ethmoidal cells. The clinical significance of the ability to establish direct heat contacts in these otherwise inaccessible areas is evident. With a short and an ultrashort wave apparatus of 500 watt output, local treatment to the head need not exceed temperatures of 102 F. Temperatures in the sphenoidal and ethmoidal regions have been even less owing to radiation losses through the inspired air. Since the temperature of the solution circulated through the applicator is elevated to 125 F., one is certain to obtain a local temperature much higher than with short waves. The author treated four cases of ozena showing the classic signs and symptoms of atrophy, crusts and fetor. Within a week the crusts became reduced, the odor disappeared and the patients were markedly improved. The results were achieved by the physiologic reactions of the diseased tissues to the local application of heat.

**Carcinoma Originating in Sebaceous Cysts.**—Collins tabulates the eighty-four instances, available in the literature, of carcinoma occurring in sebaceous cysts. The summarized data imply that sex is of little significance. The patients are elderly, the average age being 57.5 years. In twenty instances the average known existence of the sebaceous cyst had been 8.7 years. In 91.4 per cent the malignant sebaceous cysts were located on the head or neck. In 40 per cent of the patients it was necessary to perform two or more operations so as to remove the lesion completely. In thirty-four of the reported cases, 14.7 per cent were basal cell epitheliomas, but none of them arose from a sebaceous cyst situated in the scalp. This is of interest, as a study of fifty-eight of the reported malignant cases showed that 34.5 per cent had occurred in the scalp. Of the five patients having epidermoid carcinoma graded 3 and 4, two died from recurrence. Fourteen cases were graded 1 or 2, and no deaths were attributable to a recurrence of the carcinoma. In a clinical follow-up study made on thirty-four of the patients,

70.6 per cent were well; 14.7 per cent had died from recurrence of the epithelioma; 8.8 per cent could not be traced, and 5.8 per cent had died from causes unrelated to their previously removed malignant sebaceous cyst. Three cases of sebaceous cyst with malignant degeneration are reported. These occurred in some 9,000 routine examinations of all types of pathologic material, an incidence of about 0.033 per cent.

**Sudden Thrombosis of Arteries of Extremities.**—McKechie points out that emboli which involve the acral arteries originate somewhere in the proximal portion of the arterial tree, in the left side of the heart or in the pulmonary veins, except the occasional paradoxical embolus, which occurs when a patent foramen ovale is present. Thrombosis of an acral artery actually occurs secondarily to some primary process in the vessel or blood, such as embolism, degenerative processes in the wall of the vessel, inflammation, trauma or increased coagulability of the blood. Thrombosis may occur in an extremity following operation. Extension of thrombosis from small arteries close to the field of operation to the larger arteries may be the explanation in some cases. However, this does not explain the sudden thrombosis of a vessel distant from the site of operation. In these cases it is possible that increased coagulability of the blood plasma, particularly if the patient is debilitated, may be one of the factors, and stagnation of the blood, which is attributable to inactivity of a limb subsequent to an operation, is probably one of the accessory causal factors when associated with unusual conditions present at the time of operation, such as severe infection or arteriosclerosis. The pathologic changes in sudden arterial occlusion of an extremity occur in the limb or in the vessel at the site of obstruction. The changes that occur in the limb are the result of the ischemia rather than of the thrombus or embolus. The changes in the vessel in the region of the occlusion vary according to the nature of the occluding factor; thus, in thrombo-angiitis obliterans, periarteritis nodosa and bacterial arteritis, signs of inflammation are present microscopically and even macroscopically. Pain is usually the initial and most frequent complaint. Other symptoms of less frequent occurrence are tingling, tenderness, cramps, itching, pallor and burning. Absence of pulsation below a given point in an artery is indicative of arterial occlusion, if a normal arterial tree is assumed to begin with. If this absence of pulsation is associated with abnormal pallor and decreased surface temperature, the diagnosis of recent arterial occlusion is justified. The prognosis in sudden peripheral arterial occlusion is not always good, as gangrene has developed in about half of the cases studied.

**Antitoxin Treatment of Meningococcal Infections.**—By comparing the relative efficiency of meningococcus antitoxin and antimeningococcus serum, Morrison relates the experimental and clinical progress made in the treatment of meningococcal infection. The final data of Hoyne's investigations made in three hospitals show that over a period of eighteen months 319

patients were treated, 217 receiving two well known standard brands of antimeningococcus serum with 100 deaths and 102 receiving the experimental antitoxin with twenty deaths. In Levy's series of twenty-four cases treated with meningococcus antitoxin there were six deaths. His method of administration was much the same as Hoyne's. The mortality rate in Memphis over a period of nine years prior to 1933 was 57.1 per cent. In addition to the marked reduction of the mortality rate when antitoxin is used, other observations made seem pertinent. In no instance did an ocular or auditory complication develop after the institution of antitoxin therapy. The period of hospitalization for antitoxin-treated patients averaged 16.2 days, while those receiving antimeningococcus serum averaged eighteen days. A skin sensitization test should be made when antitoxin or antiserum is given intravenously, and in doubtful cases a small amount of epinephrine may be given at the same time. Usually a serum reaction occurs at about the sixth or eighth day, when it may be necessary to control the urticaria by means of epinephrine hydrochloride. The meningococcus antitoxin has a decided advantage over the antimeningococcus serum. It is believed that, as more antitoxin is given intravenously, less will have to be given intraspinally.

**Ketosis in Treatment of Epilepsy.**—To determine whether the acetone bodies developed in the course of the ketogenic diet are the factors that inhibit epileptic convulsions, Finkelman and his associates treated eleven institutional epileptic patients with diacetone alcohol. From 2 to 6 drachms (8 to 24 cc.) of the drug were given daily during two periods of treatment. The first period was from forty to fifty days and the second was fifty days. There was an intervening period of twenty-five days during which no medication was given. It was found that diacetone alcohol was not anticonvulsant in institutional epileptic patients. The urine in seven patients was positive for acetone and there was no correlation between the number and severity of the seizures and the acetone reaction in the urine. The blood sugar was increased in four patients and lowered in one. Diacetone alcohol was injected intravenously into six rabbits in order to ascertain the relation of this drug to blood sugar. It was found that there was a definite increase in the blood sugar level following the administration of this drug. The discrepancy in the action of diacetone alcohol in human epilepsy and in the thujone convulsions in rabbits is probably due to a failure of obtaining a sufficiently high ketone blood level in human epilepsy at the time a convulsive seizure is imminent. The ketogenic diet may be more efficacious in maintaining a high ketone blood level than the administration of the ketone bodies as such. However, it is more likely that the results

obtained with the ketogenic diet are due to the shifting of intracellular fluid and potassium within the cell membrane that accompanies a strongly ketogenic diet. The rise in blood sugar caused by diacetone alcohol is due to an inhibition of insulin activity which this drug probably causes.

**Passive Immunization in Experimental Rabies.**—Hoyt and his co-workers were able to build immunity in white mice sufficiently high to protect a moderate percentage of animals against intracerebral inoculation of the Cutter strain of fixed virus. An extremely high type of such an immunity may be developed against this virus when it is introduced by the intramuscular route. However, it was necessary to introduce antiserum within a relatively short interval before the inoculation of virus. Antiserum given intraperitoneally showed its greatest effect when injected four days or less before the virus. It was relatively ineffective on injection ten days before the virus and appeared entirely lacking in protective properties when administered sixteen days before the infecting dose of virus. The intracerebral administration of serum at an interval of twenty-four hours before the virus was sufficient to decrease greatly the efficacy of passive immunization. Serum antibodies can neutralize virus in vivo only if they reach the virus before it has had time to gain sufficient access to its tissues of choice.

An alternative explanation, recently discussed by Sabin, would necessitate that contact be made between antiserum and the susceptible cells either before or when these cells come into contact with the virus.

**Cancer Prevention.**—Neal states that a concerted move toward cancer prevention requires that: 1. Cancer prevention be taught by a more intensive and practical instruction of medical students on the subject of precancerous conditions and by frequent postgraduate reviews for the practitioners of medicine by men interested, qualified and enthusiastic in this field. 2. Cancer prevention should be preached by participating actively in the efforts to enlighten and instruct members of the profession and the public in matters pertaining to cancer, especially the possibilities and importance of its prevention. 3. In the practice of cancer prevention the desirability of regular and stated examinations for the detection of disease processes should be advocated. 4. Cancer should be approached from the point of view of prevention. Group team work including social, clinical and pathologic studies under suitable conditions promises much in the field of cancer investigation. The neglect of and the indifference to such studies are detrimental to the further acquisition of knowledge of cancer.

**Blood Changes in Arthritis.**—Cecil contends that of the five most common types of arthritis (gonococcal arthritis, rheumatic fever, rheumatoid arthritis, osteoarthritis and gout), with the exception of osteoarthritis, there are fairly reliable

blood tests for each: the complement fixation test for gonorrheal arthritis, the antistreptococcal test for rheumatic fever, the agglutination reaction for rheumatoid arthritis and the blood uric acid determination for gout. The least dependable of these tests is the antistreptococcal determination in rheumatic fever. The other three tests can be considered fairly reliable and practical in their clinical application. Not nearly enough use is being made of the streptococcus agglutination reaction in the diagnosis of rheumatoid arthritis. The author has found this test of great practical value in differential diagnosis. It seems fairly certain that streptococci of various types can be recovered not infrequently from the blood of patients with various acute infections and chronic constitutional disorders. In most instances they probably have little or no significance. In rheumatoid arthritis, however, streptococci can frequently be recovered from the blood, and positive streptococcus agglutination and precipitation reactions can be obtained in a high proportion of patients with the disease.

**Laparotrachelotomy.**—Conger believes that low cervical section is a much safer operation, especially in cases of potential infection. It allows a good trial of labor with comparatively little additional risk, thereby eliminating many unnecessary sections. Technically it is not a difficult operation, especially after a trial labor, when thinning of the lower segment and loosening of the uterovesical peritoneum make it a simple procedure. The numerous advantages over the classic justify the ten or fifteen extra minutes required for its performance. Patients delivered by low section are much more comfortable and are spared many grave complications attending classic delivery under the same conditions. Three of the author's patients had been delivered previously by classic sections. Following laparotrachelotomy, they were all favorably impressed by the greater comfort and smoothness of their convalescence. Low section is neither a cure-all for every case of dystocia nor a fool proof operation. Delivery of the septic patient by laparotrachelotomy will be as tragic as delivery by classic section. Patients with a temperature of 101 F. or higher should not be delivered abdominally. The history of long labor, ruptured membranes and careless vaginal examinations help in differentiating septic cases. Craniotomy in this type of case will reduce the maternal deaths. If this is refused, Porro section should be the method of abdominal delivery. The risk in the abdominal delivery in hemorrhagic cases is directly proportional to the time during which bleeding has been going

on. Refraining from vaginal examinations on prospective candidates for section will reduce the postoperative reaction even in delivery by laparotrachelotomy.

**Pain Syndromes in Upper Part of Urinary Tract.**—Keyser takes the conservative course in dealing with pain syndromes and stasis mechanisms in the upper part of the urinary tract. The indwelling catheter or dilation with bulbs has in his experience given complete to partial symptomatic relief in from 60 to 80 per cent of a series large enough (167 cases) to warrant conclusions. He is certain that many of these patients would have been subjected to nerve-cutting operations and fixations, by others and that in certain instances a greater degree of relief might have been obtained. Nevertheless, operative procedures in patients with unbalanced autonomic nervous systems are frequently unsatisfactory. Also he feels that the indwelling catheter and ureteral bougie, if used cautiously, will relieve or hold at a standstill many of these pathologic processes, so that surgery will become unnecessary. For this reason he contends that conservative ureteral dilation before resorting to surgery is a method worthy of trial, not necessarily on the basis of a high incidence of organic ureteral stricture but as a physical therapeutic attempt to readjust an unbalanced neuromotor dysfunction.

**Gonorrheal Osteomyelitis of Vertebrae.**—Woolsey reports the case of a man of 43 who was admitted to the hospital Aug. 9, 1934, giving a history of pain in the back six days previously. Physical examination was negative except for pain and slight tenderness in the upper lumbar region rather to the right of the midline. Urinalysis showed one plus albumin and many pus cells. The venereal history was negative. Roentgenograms of the lumbar spine showed moderate arthritic changes of hypertrophic type. There was no urethral discharge, nor did

pus in the urine show gonococci. Blood August 12 failed to agglutinate *Bacillus typhosus*, *Bacterium tularensis*, *Brucella abortus* or *melitensis* or *Streptococcus viridans* and gave negative agglutination tests on three succeeding examinations. The last negative culture was reported on August 28. Cystoscopy was done the following day. The bladder, ureters and kidney pelvis were negative to plain roentgenograms and pyelograms. The temperature ran from about 100 to 104 F. for the first week and then dropped down about 1 degree. During this time most of the complaint was in the region of the right kidney and was much more pronounced when the patient turned over or lay on his right side. September 12 the author felt that he could detect a slight difference on the two sides, and thought of perinephric abscess. He introduced a needle on the right side and found pus and operated the following morning. Intracellular and extracellular gram-negative gonococci were found, and complement fixation for gonococci was plus four. The following morning roentgenograms demonstrated destruction of a large portion of the vertebra in contradistinction to the last picture taken ten days previously. Following the operation the temperature dropped perceptibly, the pulse rate remaining about the same. By September 25 the white count was 8,350 and the red count was 1,350,000 with a hemoglobin of 40 per cent. The patient was given a transfusion, which was followed by a chill and a temperature of 107 F., after which improvement was satisfactory. October 19, roentgenograms showed destruction of half of the second lumbar vertebra. From the time of operation the patient was carried on a Bradford frame until November 15, when a cast was applied in hyperextension, opening in the back for dressings. The temperature ranged to 100 F. each day. He complained of more or less pain in the region of the bladder and on micturition. By January 1 this became so pronounced that irrigations were made daily. January 9 the strictured urethra was dilated under cocaine, after which a retention catheter was left in place for a week with daily irrigations. Occasional constant drainage for a few days and irrigations almost daily were necessary until April 1. May 7 a Taylor brace was applied and the patient was allowed to sit up. In a short time he was getting around very nicely. He left the hospital June 16, 1935, with very little fever and a normal blood picture. September 17, gonococcus complement fixation was still four plus.

**Diagnostic and Therapeutic Possibilities of Roentgenology in Infant Mastoiditis.**—Crain and Sloan present twenty cases of infant mastoiditis that stress the diagnostic possibilities of roentgenology and present the possibilities of roentgen therapy. The percentage of mortality in the cases presented is much less than that reported for surgery or non-surgical cases. All patients were less than 26 months of age,

and all had roentgen evidence of mastoid infection. Relatively fewer infants have been operated on for mastoiditis by the authors since roentgen therapy has been tried. The roentgenogram of an infant mastoid will show a fairly constant type of development for a given age. The semicircular canals which are visible in the younger infant begin to lose their identity as age progresses. The antrum is often not visualized, owing to presence of embryonic tissue within it, but its form is generally outlined to some degree. There is no cellular development, but there is a distinctly outlined "premastoid" area visible posteriorly and inferiorly from the antrum. This area is composed of cancellous bone, which shows the trabeculations observed in other cancellous bone. It is roughly triangular, but as development progresses it assumes a spherical or ovoid outline. The lateral sinus is not normally visible in the infant mastoid. When infection takes place in the middle ear of an infant, it easily finds a pathway to the antrum, from which point it can readily infect the cancellous tissue of the pre-mastoid area. When the infection is confined to the antrum, it may be possible to demonstrate a definite cloudiness of this area. A comparison with the opposite side is essential, as the normal antrum may be cloudy. If the infection involves the cancellous "premastoid" area, there are visualized changes, which in this structure are comparable to the changes that may be observed in the pneumatized mastoid. There may be a haziness of the region; the trabeculae may be fuzzy, thickened or absorbed. As the infection progresses, there is absorption of bone and the lateral sinus becomes visible, a positive sign of destruction in the infant mastoid. Roentgen irradiation is beneficial, is often curative, and has a definite place in the treatment of this condition. The benefits of radiation therapy in infant mastoiditis arise from the direct action of radiation on acute infections and from its indirect effect on the pathologic process by the production of drainage. Embryonic tissue is extremely radiosensitive, and it is reasonable to suppose that sufficient dosage of x-rays will cause a shrinking of this tissue and will, in fact, produce a nonsurgical drainage of this area. Collections of adenoid tissue about the pharyngeal opening of the eustachian tube may also block drainage. Lymphoid tissue is also radiosensitive and it is possible that this will shrink and promote adequate drainage from the middle ear.

**Prolonged Continuous Sleep Treatment.**—Day employed the prolonged continuous sleep method of Witt and Cheavens in treating various cases of mental disorders. Each drachm of the standard sleep mixture contains 1 grain (0.065 Gm.) of phenobarbital sodium and 5 grains (0.3 Gm.) of barbitol sodium dissolved in peppermint water and colored red. Two drachms (8 Gm.) of this mixture is usually given every four hours until sleep has been induced, then 1 drachm (4 Gm.) often enough to maintain the desired state of somnolence, which varies usually from one to six times in twenty-four hours. Fecal impactions are guarded against by a daily soap-suds enema, magnesium sulfate once a week, and two or three ounces of vegetable oil. Attention to food is second only to caution against barbitol poisoning in these patients. They eat much better when undergoing continuous sleep treatment, and, while they have to be spoon fed, much patience and time are devoted in giving them nourishing food, of a nonresidue character. In cases of serious emaciation, persistent vomiting or unusually severe agitation the patient is rendered completely comatose and tube fed two or three times a day. Tube feedings consist of milk, eggs, sugar, salt, vegetable oil, tomato juice and brewers' yeast, about 1,800 cc. daily, containing from 2,300 to 3,000 calories. After this type of therapy, manic and depressed patients awake, almost without exception, refreshed and rested, with a considerable gain in weight and a completely new outlook on life. This improvement usually progresses to complete recovery in a short time. Schizophrenic and involutional psychotic patients frequently show the same type of improvement for from three to ten days and then begin to regress. Patients having involutional melancholia, hysteria, anxiety states or maladjustments show very little improvement. The results are so uniform that one can almost make a diagnosis by the patient's course after continuous sleep treatment. Hysterics are not nearly so uniform. The average duration of sleep was 20.4 days, the shortest being three days and longest seventy-eight days. The author believes that in manic

patients the elevation of mood leads to an extravaganza of ideas and both lead to greatly increased motor activity. Increased motor activity stimulates an increase of mental activity and thus a vicious circle of cause and effect is developed. Sleep breaks this vicious circle. It is also probable that the undernourishment and cerebral impoverishment which result from lack of food and increased psychomotor activity further aggravate the mental aberration, producing another vicious circle, which is interrupted by the increased food intake and reduced activity under continuous sleep treatment. The depressed patients seem to derive their beneficial results from the long respite from their unhappy, melancholy thoughts. Involuntional depressions seem to derive somewhat the same result, although the author is convinced that involuntional psychoses are organic, probably endocrine, in origin rather than purely affective. In schizophrenia the disorder is one of intellect. Therefore nothing more than transitory improvement due to temporary relief from thinking can be expected.

**Cervical Rib and Anterior Scalene Syndrome.**—Flothow has recently seen several patients in whom the symptoms of brachial plexus irritation have been due to anatomic anomalies of the supraclavicular triangle. The anterior scalene muscle by virtue of its relation to the first rib and the brachial plexus and subclavian artery may produce symptoms similar to those of cervical rib. Treatment of the condition, the anterior scalene syndrome, is section of the anterior scalene muscle. The operation of tenotomy of the anterior scalene muscle has replaced that of resection of cervical ribs which are causing symptoms. This operation is much safer, is unaccompanied by unfavorable postoperative sequels and gives more satisfactory results than resection of the rib. Four cases are presented: one of definite cervical ribs, one of rudimentary nubbins of ribs and two of the anterior scalene syndrome in which tenotomy of the anterior scalene muscle has been performed. In the one case with definite cervical ribs the result has not been very satisfactory. The history was atypical and it is probable that the ribs were not causing all the symptoms of which the patient complained. There has been some improvement, but many of his complaints persist. In the three cases without cervical ribs the results have been excellent.

**Radiology of Facial Bone Fractures.**—Hodgson asserts that the most certain method of recognizing fractures of the facial bones is roentgenologic, but, unless the examination is carried out with a full knowledge of the anatomy of the parts and the mechanics of this type of fracture, the injury may even then escape notice. The roentgenologist has to take into account the direction of the force, visualize the plane of the possibly resulting fracture and take roentgenograms so as to view it tangentially, and with the correct degree of roentgen penetration to throw the particular bone or bones concerned into relief. The stereotyped anteroposterior and lateral roentgenograms of the skull will show one little or nothing of this type of injury, and special views have to be taken with this particular object in view. In fractures of the nasal bones the axial view is taken with the chin resting on the film and the head thrown back at an angle of 30 degrees with the horizontal, the tube being tilted 30 degrees toward the feet. This causes the central ray to pass axially down the nose, giving one an "end on view." In fractures of the malar bones only by directing the rays at right angles to the line of force, as described in the axial view of the nasal bones, can one see that the lower orbital margin has been fractured through the foramen and the whole of the malar portion displaced bodily backward into the antrum. The best view to show fractures of the zygoma is the verticomental view, the rays being centered at right angles to the vertex. Fractures close to the symphysis are often concealed in an anteroposterior view, as the shadow of the cervical spine is superimposed. They are best shown by rotating the patient's head slightly to one side and directing the rays obliquely upward on to the film. A fracture of the horizontal ramus is best shown by directing the rays obliquely upward, so as to throw the uninjured jaw clear of the injured side. The temporomandibular joint is well seen if the head is placed in the lateral position, with the injured side against the film and the rays directed downward at an angle of 30 degrees.

**So-Called Spontaneous Arachnoid Hemorrhages.**—Bouman believes that subarachnoid hemorrhages caused by leakage from aneurysms, called spontaneous because the underlying cause is unknown, are comparatively frequent. The conditions that favor the origin and growth of such aneurysms are discussed. Apart from cases in which in advanced age arteriosclerotic changes of the vessels are evident, cases showing precedent syphilitic infection or those in which an injury of the skull has brought about a rupture of the blood vessels, so-called spontaneous hemorrhages in young and otherwise healthy persons are difficult to account for. Such bleedings in young persons are usually supposed to be due to some developmental defect, but this defect cannot be—in the author's opinion—a so-called congenital weakness of the vessel wall. He is convinced that there must be another cause behind all this to explain that weakness and the eventual rupture. This ultimate cause may be the real congenital factor. Ruptured aneurysms in young persons are mostly—at least in his postmortem cases—accompanied by a variation in the ramifications of the blood vessels. The frequency of this anomaly is undoubtedly much greater than in other varieties of brain disease. These variations in the ramifications of the circle of Willis are mostly of the same type. This coincidence of congenital variations and spontaneous bleedings cannot be accidental. If this is right, he believes that one must conclude that in the case of such anomalies the conditions of the blood currents in the circle of Willis have changed completely and that the normal static and dynamic conditions are disturbed greatly. If the normal communication between the basilar artery and the arteria cerebri posterior is blocked (or almost blocked) on one side, the whole current is led through the arteria communis posterior on the other side. But this relatively small vessel is also subjected to the high pressure of the internal carotid. The effect can only be that two mighty currents of the blood circulation meet together in this small vessel, originally not built to resist these currents. Moreover, this particular vessel is subjected to the entirely opposed currents of the internal carotid and the basilar artery. As soon as the wall is weakened by the perpetual currents, an aneurysm may easily be formed and increased by whirlpools made by these directly opposed currents. Hence the "supposed weakness" of the vessel wall. There can be only one end of this process, viz., the so-called spontaneous rupture of the vessel. In this way the arachnoid bleedings in young and otherwise healthy persons may be satisfactorily accounted for.

**Vaccine Treatment of Typhoid.**—Krishnaswamy Rau and Krishna Rao state that they have recorded as high as 84 per cent of success in cases in which intravenous triple vaccine was

started in the first week of illness. On the other hand in late second week cases, when the patient is in a state of toxemia with signs of toxic myocarditis, they hesitate to give triple vaccine intravenously for the obvious reason that the shock produced might be followed by unfavorable results. In such cases they prefer giving the vaccine intramuscularly; some respond well, others do not show much reaction. This explains the lower percentage of success in their series of second week cases. Thus triple vaccine given intramuscularly has its own advantage and it is not too much to infer that it presents complications both early and late, clears the toxemic condition quickly, improves the general condition of the patient and brings about a modification in the range of temperature, though it may not cut short the course of the fever in all cases. The average adult dose varied from 50 to 100 million organisms intravenously and from 100 to 200 million organisms intramuscularly. The dose usually employed in children between 8 and 12 years of age is 50 million organisms intravenously. The dose and the route of administration have to be determined in each case by taking into consideration the degree of toxemia, the day of the disease, the condition of the myocardium, the temperature, the age and the general condition of the patient.

**Study of Hypochondriasis.**—Brown regards hypochondriasis as a reaction of the individual to a difficulty rather than as a disease. The incidence of body complaints in the 226 admissions in 1934 to the Phipps Clinic was 45 per cent. The nature and etiology of the body complaints is discussed in forty-one cases showing hypochondriasis in anxiety and obsessional states, hysteria, invalid, schizophrenic and depressive reactions. These body complaints were classified mainly on a basis of affect and attitude to illness into psychoneurotic or mergergic hypochondriasis, schizophrenic or parergastic types of hypochondriasis and depressive hypochondriasis. A great difficulty of this problem lies in defining the meaning of the emotional states, such as depression, anxiety, fear and tension, and in deciding what are the physical accompaniments. It is probable that the body complaints in all these conditions are related, and some kind of classification is necessary to understand and treat the psychogenic body complaint, which seems to have as many ramifications and complexities as the physical body complaints, which are the province of organic medicine.

**Hematology of Convulsions.**—Guirham studied the hematology of eight epileptic patients and two control subjects. The individual observations were continued for a period of from twenty-one to sixty-four days. A definite hemocytic variation was observed with the incidence of the convulsions. It is not, however, uniform in tendency in all cases, which seems to indicate that there are characteristic pathologic variations for epileptic patients but not for epilepsy. The white cell count is markedly variable in epilepsy, its greatest variability being at the time of the convulsion. There is a definite leukocytosis associated with the occurrence of fits. It is due, in practically all cases, to a relative increase in the lymphocytes. Eosinophilia, traditionally associated with epileptic convulsions, occurred but rarely. Eosinophilia is found in that minority of cases in which the increased white count, associated with fits, is due to the polymorphonuclears. When fits occur in

groups, there is a tendency for a low count to be associated with a period of fits. The red cell count and hemoglobin percentages vary, in association with the convulsions, but to a less degree than the leukocytes. There is an increase in the erythrocyte count at the time of the fits. This may or may not be accompanied by an increase in the hemoglobin percentage. There appears to be no very definite relation between the type of cell count and the degree of frequency of the fits. No real evidence of a daily leukocyte tide was afforded by a study of the control subjects, or of the epileptic patients in a quiescent phase.

**Normal Leukocyte Picture in Hot Climate.**—Investigations of the polymorphonuclear count of European and indigenous populations in Irak showed a marked shift to the left. This directed the attention of Kennedy and Mackay to the differential count, and it was found that the blood picture in normal persons in Irak differed from the standards given in all the textbooks of tropical medicine available to them. These, indeed, were similar to the figures found in the best known manuals of histology, pathology and medicine. Physiologic standards were necessary for the furtherance of other researches. Differential white cell counts and polymorphonuclear indexes of 271 British airmen and twenty-nine Irak medical students, under subtropical conditions, are presented and analyzed. Evidence of bone marrow stimulation appears to be afforded by deviation of the polymorphonuclear count, the frequency of "abnormal" cells and the high total count. A left-handed polymorphonuclear index could result from increased removal from the circulation, and this is probably a factor, but there is no evidence that it is operating alone. If it did, an unstable state would result, and on the contrary an equilibrium was demonstrated by the similarity of repeated counts in random individuals, the absence of double maximums in any count and the nonoccurrence of leukopenia. The very high figures obtained for monocytes indicate that these cells are more sensitive to the hematopoietic stimulus at work than the granulocyte series or that they are more resistant to the probable increased removal of white cells from the blood stream, or both. In certain pathologic conditions, *e. g.*, phlebotomus fever, much higher monocyte counts were found. The possible causes are discussed, and it is concluded that the climate is most probably responsible.

**Dietary Deficiency, Nerve Lesions and Dental Tissues.**—King compared the effects of resection of certain nerves with those due to vitamin A deficiency. The vasomotor system exerted an influence on the growth of the teeth. In dogs receiving diets deficient in vitamin A the eruption of teeth was delayed, hypercementosis occurred and the laminar durae and bone of the tooth sockets were malformed and the alignment of the incisor teeth was irregular, in addition to periodontal and nervous defects. When the inferior dental nerve was resected on one side, the eruption of teeth in dogs and

the growth of teeth in rabbits was accelerated and the alignment of the incisor teeth was irregular; but no defects in the dental or periodontal tissues were found. As similar changes were observed on resection of the cervical sympathetic, the effects of severing the inferior dental nerve are regarded as due to damage to vasomotor fibers in it.

**The Spa in Treatment of Rheumatic Diseases.**—Buckley points out that one of the most important features of treatment at a spa, whether in a hospital or privately, is the combination of rest and recreation in health-giving climates and attractive surroundings. This is of the utmost importance, which must always give to the spas advantages over treatment in large centers of population. Some consideration must be given to the difference in the effect of the various mineral waters. The analysis of a water throws but little light on its therapeutic action and one must depend largely on clinical observation supplemented by the work of the biochemist. The effect of a course of mineral water drinking may be due to purgation, cleansing the intestinal tract and removing toxins; this will be the effect of the strong sulfur and saline waters; to diuresis associated with flushing of the tissues generally or, perhaps vaguely, to stimulation of metabolism, of which there is both clinical and experimental evidence. In most rheumatic conditions, however, the external use of water in the form of baths, douches and other methods is generally considered to be the more important. The effects are due to thermal, mechanical and chemical action. Thermal effects will be the same whatever the character of the water employed and will influence rheumatic conditions by improving the flow of blood especially in the cutaneous vessels and at the periphery. Mechanical effects, while produced equally by plain water when used for douches, will in baths depend on the nature of the water, the strongly saline and the gaseous waters producing definite effects peculiar to themselves, and these merge with the chemical effects. Physical treatment, of which spa methods are one of the principal forms, must always be of the utmost importance in the treatment of rheumatic diseases.

 Idiopathic Steatorrhea with Multiple Nutritional Deficiencies: Case. H. W. Fullerton and J. A. Innes.—p. 790.

**Botulism.**—In the case of Aitken and his associates bacteriologic examination of the suspected food—an open meat pie—confirmed the diagnosis and yielded a strain of *Clostridium botulinum* producing a type B toxin. This is the first recorded instance of a type B strain producing botulism in England. The potency of the toxin it produced in the pie was evidently high. The strain grows poorly and is feebly proteolytic and saccharolytic. Its anaerobic growth is greatly improved by the addition of 10 per cent carbon dioxide to the atmosphere in the jar, and it is suggested that incubation in this atmosphere be included in the routine procedure for the isolation of *Clostridium botulinum*. The type B strain isolated is

toxinogenic in relatively dry mincemeat, exposed even more freely to air, without the aid of symbiotic aerobes that is usually postulated as a necessary factor in the aerobic growth of *Clostridium botulinum* under domestic conditions.

**"Specific" and Nonspecific Treatment of Boils.**—Klüber asserts that the continued recurrence of boils is dependent in most cases on underlying factors. Treatment directed toward the removal of such conditions is therefore not only rational but usually highly successful. It consists of the removal of local sources of mechanical friction and secondary reinfection (hot fomentations, mechanical appliances, infected clothing), the removal of substances obstructing the opening of the follicles (dirt, oil, acne comedones), the treatment of septic foci (dental abscess, antral infection), the treatment of underlying cutaneous disorders (acne vulgaris, seborrhea, lichen urticata, eczema, scabies, pediculosis, pruritus) and the treatment, when present, of hyperglycemia, anemia, malnutrition and the like. Some cases appear to be associated with anxiety or "overwork." It is often impossible to separate the physical and psychologic factors concerned. Increased fresh air and sunshine or a long holiday may be followed by remissions. So many cases, however, improve following general ultraviolet irradiation that it seems probable that the immunity of the skin to the staphylococcus is in some way increased by the treatment. Roentgen treatment is of great value in the case of axillary boils and those confined to the face, neck and other areas commonly affected by acne vulgaris. This is the most reliable method of diminishing the excessive sebaceous and horny secretions responsible for these conditions. The retention of these products in the follicles invites recurrent infection by the staphylococcus. The virtue of any "specific" treatment for recurrent boils is peculiarly difficult to assess, owing to the irregular character of this affliction. The reinvestigation of seventy-nine cases treated by nonspecific methods (especially general ultraviolet irradiation and x-rays) from two to three years earlier indicated serious persistence in only three cases, in which there was an underlying chronic skin disorder. The results obtained by the use of toxoid in twenty cases of sycosis and thirteen cases of boils were not sufficiently encouraging to justify a continued trial. The injection of staphylococcus toxoid constantly increased the circulating antihemolysin. There was no evidence, however, that this increase had any clinical value.

Inductotherm. E. P. Dark.—p. 397.

**Metabolism of Calcium and Phosphorus in Acromegaly.**—Cox and McPhee observed no disturbance in the metabolism of calcium or of phosphorus in three cases of acromegaly. Case 1 is advanced and almost certainly nonprogressive, showing a marked general osteoporosis and resembling the type encountered in certain cases of hyperparathyroidism. Case 2 is early and probably progressive, showing no osteoporosis. Case 3 is advanced and progressive, also showing no osteoporosis. The two advanced cases both show the usual bony changes of their disease in that the bones have increased in size, have widened by the laying down of new bone beneath the periosteum, and many new bony formations are present. In case 1 the bones, having attained the usual contour of those found in acromegaly, yet have undergone rarefaction. Thus the calvarium, which is much increased in width, is definitely rarefied and has not the density usual in acromegaly. The thickened cortices of the long bones have undergone a similar rarefaction, a process that has extended even to the osteophytes. Thus it is the progressive case which shows the usual increase in density of bone, while the nonprogressive case shows rarefaction. It is suggested that a deficiency of calcium in the diet may have resulted in a call being made on the bony tissues. A generalized decalcification of bone is known to occur in thyrotoxicosis. No evidence of thyrotoxicosis was observed. In the light of such knowledge as is possessed as to the causes of generalized osteoporosis, it would seem likely that the decalcification has resulted from some imbalance of the endocrine glands. The biochemical investigations do not support this interpretation. In view of

the association of the parathyroid secretion with the mobilization of calcium, the possibility must be considered that in case 1 the parathyroids were overactive either intermittently or continuously and that this aberrant function could not be detected by the biochemical methods used. Furthermore it is possible that, while hyperfunction of the parathyroids may have been present during the progressive phase of the pituitary tumor, a normal state may have existed during the retrogression of the latter. Moreover, it cannot be dogmatically stated that the secretions of the pituitary and parathyroids are alone necessary for the mobilization of calcium. Knowledge of the exact chronic state in which calcium exists in the blood and tissue fluids is far from complete.

\*Tuberculin Purified Protein Derivative in Treatment of Tuberculosis. B. C. Thompson.—p. 27.

**Tuberculin Purified Protein Derivative in Treatment of Tuberculosis.**—Thompson used tuberculin purified protein derivative in fifty-four cases of cervical gland tuberculosis and obtained improvement in thirty-two cases. In thirteen cases there was considerable reduction in the size of the glands, in ten cases there was great reduction, and in nine cases the glands were almost impalpable. These results are not necessarily permanent: nine of these patients are still under treatment, but their present state indicates a tendency to improve rather than otherwise. No improvement was produced in eighteen cases, in ten of which the disease went on to abscess formation and in two others, after temporary reduction in size, extended to other adjacent glands. In four cases purified protein derivative treatment was abandoned, owing to refusal of further injections or neglect of attendance by the patient. These results compare unfavorably with a series published previously of forty-two cases of cervical gland tuberculosis treated with Beranek's tuberculin. Of the latter, thirty-two cases which came under treatment prior to gross caseation improved or became arrested over a long period. Though the results in the earlier stages were significantly better than those in the present series, local reactions were usually less severe and general reactions seldom occurred, therapeutic effect being obtained at a lower level of dosage. This suggests that the power to produce focal reaction, on which therapeutic value partly depends, is relatively

higher in Beraneck's tuberculin than in tuberculin purified protein derivative, and that purified protein derivative used as an intradermal test should be safer than old tuberculin as regards the possibility of lighting up latent tuberculous foci.

**Diphtheria Antitoxin in the New-Born.**—Magara states that antitoxin of diphtheria is transmitted to the embryo through the placenta, and therefore approximately 73 per cent of the new-born infants are inherently immune from diphtheria. But since the antitoxin in the blood of sucklings disappears rapidly, not all the sucklings are immune to diphtheria during the first six months after birth, as it has been believed. The injection of anatoxin into new-born infants is not sufficient, because they respond feebly to its injection. When pregnant women are given the injection of anatoxin, even a small amount of anatoxin causes antitoxin to increase to a much higher degree than in normal women, without any accompanying accessory reaction, and in addition the antitoxin in the blood of mothers is transmitted to the embryo through the placenta in almost the same quantity. Because even in those pregnant women who had no antitoxin before injection, antitoxin definitely appears with two courses of immunization through the injection of anatoxin given at monthly intervals, the offspring born of immunized mothers are highly immune from diphtheria. In spite of the fact that their antitoxin is of a passive nature, it lasts over a comparatively long period because it is constantly supplemented by the antitoxin contained in milk and completely protects such infants from diphtheria for at least half a year to a whole year after birth. The antitoxin in the blood of such mothers remains unreduced for half a year and therefore immunizes the next offspring born within one or two years. Pregnant women who are immunized with anatoxin secrete from 0.01 to 0.02 unit of antitoxin into their milk continuously for more than six months.

**Sulfamides in Treatment of Erysipelas.**—Bloch-Michel and his co-workers studied the effect of para-amino-benzene sulfamide on mice infected with virulent hemolytic streptococci and on patients with erysipelas. With the mice, the effect was more marked when virulent strains were used; with strains of mild virulence, the effect was almost absent. However, the results with mice were variable, depending on the virulence of the strains, the quantity of germs inoculated, the time that separated the inoculation from the treatment and the mode of treatment itself. None of the treated animals were immunized; the survivors were just as sensitive to subsequent streptococcal infection as previously. The clinical observations were made on 250 patients with erysipelas. Treatment of most of these with sulfamide derivatives certainly modified the evolution of this disease. The action was particularly good on the temperature and on the erysipelatous plaques. Furthermore, sulfamides given at the onset of the erysipelas seemed to diminish the number of complications but had no action on the suppurations once they became established.

- Mortality from Diphtheria. M. Moine.—p. 1604.
- \*Rational Treatment of Epilepsy. C. Adler.—p. 1607.

**Treatment of Epilepsy.**—Adler describes a method of treatment which he believes is satisfactorily based on the most plausible theory of the pathogenesis of epilepsy. It consists in the use of one or more barbitol derivatives combined with caffeine in small and divided doses. These can be continued for long periods without injurious results, and it is best by gradual increase to determine the optimal dose for complete elimination of epileptic manifestations. Some variation in the time of administration of the fractional doses may be introduced, depending on the usual time of origin of epileptic attacks. By this means it is possible to inhibit completely the so-called epileptic center and to avoid all secondary manifestations in a person suffering from chronic epilepsy. This inhibition can be definitely maintained without further treatment in about 12 per cent of the patients. The only plausible hypothesis explaining this, according to the author, is that the "epileptic center," if maintained for a sufficiently long time (from eight to fifteen months) under the influence which inhibits it, eventually develops a new habit which prevents it from continuing to react to the cause or causes which previously influenced it.

### Schweizerische medizinische Wochenschrift, Basel

66: 1105-1152 (Nov. 14) 1936. Partial Index

- \*Medication with Vitamin A in Hyperthyroidism. I. Abelin.—p. 1106.
- Genital Hemorrhages During Last Months of Pregnancy. A. Couvelaire.—p. 1116.
- \*Spontaneous Change of Sex in Hermaphrodite. J. Halban.—p. 1130.

- \*Therapy of Habitual Abortion. P. Jung.—p. 1137.
- Treatment of Puerperal Fever. H. Knaus.—p. 1141.

**Medication with Vitamin A in Hyperthyroidism.**—Abelin directs attention to experimental studies on the effects of the vitamins on hyperthyroidism, particularly the experimentally demonstrated antagonism between vitamin A and thyroxine. The discovery of this antagonism led to studies on the vitamin A supply of patients with hyperthyroidism and also to the therapeutic application of vitamin A in hyperthyroidism. He mentions several vitamin preparations and then takes up the question of the auxiliary treatment, pointing out that vitamin A is a good adjuvant in the medication with iodine and with diiodotyrosine in that it greatly lessens the "crisis"

and the temporary exacerbations that ordinarily occur in these forms of medication. The author admits that a definite evaluation of vitamin A therapy in hyperthyroidism is not possible as yet.

**Spontaneous Change of Sex in Hermaphrodite.**—Halban relates the history of a true hermaphrodite with virile habitus, in whom a sex transformation toward the female habitus took place at the age of 30. The author is unable to give an explanation of the cause of this transformation, yet he thinks that the case has clinical significance, because it demonstrates the possibility of a spontaneous transformation of the sex of a hermaphrodite. He points out that this should be kept in mind in case of reports about sex transformations of hermaphrodites by means of operations or of endocrine therapy.

**Use of Ecboolics.**—Hüssy warns that ecboolics should not be used (1) in case of a disproportion between fetus and pelvis, (2) in case of threatened rupture of the uterus and (3) in case of normal labor pains. During labor it is better to give small than large doses, for they are less dangerous and just as effective as the large ones. Ecboolics should be given only if the uterine contractions are too weak and too far apart. The author recommends chiefly quinine for the period of dilatation and solution of posterior pituitary for the period of expulsion. Ergot preparations should not be given during these two periods. During the after-birth period, ergot and posterior pituitary preparations should be given together. At this time the larger doses are not only permissible but advisable. In the course of abortions, quinine and pituitary preparations may be tried, provided the hemorrhage is not too severe. Ecboolics are not suited for inducing labor in a uterus not yet undergoing contractions.

**Therapy of Habitual Abortion.**—Jung followed Sellheim's suggestion to try serum from healthy pregnant women in the treatment of habitual abortion. Sellheim in turn had been induced to make this suggestion by Mayer's report (in 1910) about the possibility of curing pregnancy toxicooses by means of the injection of the serum of healthy pregnant women. Jung, instead of using the serum, decided to use the whole blood. He gives brief clinical histories of nine women, who had had from two to six abortions previous to the pregnancy during which they were given the injections. The histories indicate that 10 or 20 cc. of blood was given by intramuscular injection at intervals of from two to six weeks. Others give the injection at shorter intervals (four or five days). The total number of injections varied in the different cases. Occasionally, when pregnancy blood was not available, progesterin was injected instead. The author emphasizes that this treatment cannot be expected to be successful in all cases of repeated abortions. He employed it only in cases of obscure etiology in which definite causes could not be found. The case histories indicate that it was successful in nearly all cases.

Gastric Secretion in Liver Diseases. F. Quaglia.—p. 457.

**Gastric Secretion in Liver Diseases.**—Quaglia reports the results of examinations on the gastric secretory functions and on the behavior of the gastric chemistry in 386 cases of liver and biliary diseases (cholelithiasis, cholecystitis, angiocholitis and cirrhosis). The author believes that achlorhydria and hypochlorhydria of different intensity, generally in association with a diminished gastric secretion, are found in liver and biliary diseases in 70 or 80 per cent of the cases. Normal chlorhydria and hyperchlorhydria are rare. The latter depends on the coexistence of gastric ulcer or duodenitis. The mechanism that induces the gastric functional or anatomic lesions which cause achlorhydria and hypochlorhydria is unknown. Its origin is related to different factors, such as diet, infection, disturbance of the acid-base equilibrium between the gastric secretion and the bile and a dysfunction of the sympathetic nervous system.

**Renal Threshold in Normal Pregnancy.**—Addressi determined the renal threshold in normal pregnancy by testing the permeability of the kidney to dextrose in induced hyperglycemia. Especial care was taken that the women tested had normal kidneys. The threshold is lowered in the last half of pregnancy, as proved by the increased permeability of the kidney to dextrose in the test. The lowering of the renal threshold can take place in normal conditions. It is dependent on several factors, such as the secretory functions of the renal epithelium, the predominance of the vagal over the sympathetic tonus in the renal innervation, the influence of insulin secreted by the pancreas and the reaction of the kidney to hyperglycemia. In pregnancy the condition is caused by an increased tonus of the vagus in the segment that innervates the kidney. The vagal disturbance originates in the endocrine and sympathetic modifications that take place during pregnancy. If the vagal tonus is exaggerated, spontaneous glycosuria, without hyperglycemia, appears. If it is not exaggerated, the renal threshold decreases and the stimulation of induced hyperglycemia suffices to permit the passage of sugar from the blood to the urine.

**Action of Gastric Mucin.**—Bonorino Udaondo and his collaborators report the results of experiments made to verify the mechanism of action of gastric mucin in neutralizing gastric acidity. They tested, in vitro, the protective action of gastric mucus by its influence on pepsin, sodium hydroxide and hydrochloric acid. They found that a 1 per cent solution of gastric mucus (neutralized in diluted hydrochloric acid and an alcoholic solution of phenolphthalein) permits digestion of albumins (in an albumin solution) by pepsin. One cubic centimeter of a tenth normal solution of sodium hydroxide to which a small amount of gastric mucus in powder had been added required 0.93 cc. of tenth normal hydrochloric acid to be neutralized, thus showing that it fixed 0.7 cc. of sodium hydroxide in each cubic centimeter of the solution. The same amount of sodium hydroxide was fixed by gastric mucus in solution. Gastric mucus in powder did not cause fixation of hydrochloric acid. Gastric mucus in solution causes slight fixation of hydrochloric acid. The authors conclude that the protective action of gastric mucus fails in controlling the effects of pepsin and that gastric mucus acts as a buffer to alkalis and acids. The action of gastric mucus in protecting the gastric mucosa against chemical constituents of gastric secretion is of little value in comparison with its influence on physical factors.

**Methemoglobinemia After Poisoning with Ethyl Nitrite.**—Seggel describes the symptomatology that developed in four workers who, for from forty-five to sixty seconds, were

exposed to the inhalation of ethyl nitrite. They were barely able to leave the room in which the gas was escaping, and they had severe dyspnea. Oxygen was given at once and the men were hospitalized. On arrival at the hospital, one hour after the poisoning, the skin and the mucous membranes of the patients showed a peculiar chocolate-brown to violet color. From the fact that the poisoning had been caused by a nitrite ester, it was assumed that a methemoglobin poisoning existed. The blood was tested for the presence of methemoglobin by a simple method which, although not exact, is nevertheless adequate for clinical purposes. The method, not hitherto used for the detection of methemoglobin, is based on the principle of the determination of the layer thickness, in which a certain line of absorption just disappears. On the first day the examination of the blood revealed methemoglobinemia, but on the second day it had disappeared. Methemoglobinuria was never observed. However, the development of a splenic tumor and an increase in the bilirubin content of the blood indicated a decomposition of the methemoglobin in the hepatolymphatic system. The relatively mild poisoning caused no lasting defects.

**Abdominal and Idiopathic Porphyria.**—Kämmerer and Meyer accept Micheli's classification of porphyrias into idiopathic and toxic forms. The idiopathic forms may become manifest with an abdominal, nervous or cutaneous symptomatology. The term idiopathic indicates the predominance of constitutional factors, whereas, in the toxic forms, infections or toxins play the chief part. The authors give their attention to the idiopathic form of porphyria in which the abdominal symptoms predominate. They describe the history of one case in which the daily quantity of urine contained 1,200 micrograms of coproporphyrin. Uroporphyrin was present only in traces. When the patient was given food that contained large amounts of blood pigment, the coproporphyrin content of the urine increased considerably; when a "porphyrin-free" diet was given, it decreased. It appears that protoporphyrin is absorbed in the intestine but that the liver fails to effect further decomposition and instead changes it to coproporphyrin. The authors think that a disturbance in a partial function of the liver is responsible for this. They assume that milder cases of a more or less isolated disturbance of the porphyrin metabolism are more frequent than has been believed and that they are usually accompanied by disturbances in the sympathetic nervous system. It appears that in such cases a greater intestinal putrefaction results in the formation of more than average amounts of porphyrin, which in turn represent an excessive load for a deficiently functioning liver. Restriction of foods containing large amounts of blood pigment and regulation of the intestinal function are the chief therapeutic requirements in these cases.

**Respiratory Pyelogram.**—According to Hilgenfeldt, the respiratory excursion of the kidneys may be demonstrated and measured by means of pyelograms taken from a patient in recumbent posture on complete expiration and inspiration. A single or two separate plates are sufficient. The author presents the respiratory pyelogram as a new diagnostic method in urology. He found the method valuable in (1) the diagnosis of pelvic and ureteral stones, particularly in differentiating shadows of other than calculous origin; (2) in localization of foreign bodies; (3) in recognition or differentiation of inflammatory conditions of the kidney and of the renal fossa, in paranephric abscess, woody phlegmon, renal carbuncle and pyelonephritis, and (4) in determining the relation of the renal fossa to neighboring inflammatory states, such as pancreatitis, appendicitis or tuberculosis. The alteration in renal excursion, however, is only a symptom to be interpreted along with other clinical and urologic investigations. It may be of aid in a

difficult diagnosis of renal disease, it may furnish supporting evidence or, on the other hand, it may aid in ruling out kidney involvement.

**Gastroduodenal Perforation.**—Paas reports from von Haberer's clinic a case of a duodenal ulcer perforation and one of a gastric ulcer perforation, occurring in the course of a roentgenologic examination with the aid of a contrast meal. The cause of perforation, he believes, is the overloading of the stomach with the contrast meal, the increased motor activity with the contractions of the longitudinal and the circular muscle fibers bringing about the rupture of the thinned out wall. He believes that manipulation of the abdominal wall plays a subordinate part in the rupture. He had observed a prolonged pyloric spasm in dogs in which he had produced an artificial tear in the anterior duodenal wall close to the pylorus. This spasm lasted for several hours and prevented the passage of the gastric contents into the duodenum and from there into the preperitoneal cavity. It required the administration of large amounts of the meal and the production of a large tear in the anterior wall of the duodenum to bring about the effusion of considerable amounts of the meal into the free peritoneal cavity in the course of the first few hours. This fact explains the better prognosis of the duodenal perforation after administration of a contrast meal as compared with that of perforation of a gastric ulcer. Injection of from 50 to 140 cc. of barium sulfate in the peritoneal cavity caused death within twenty hours in the ten dogs experimented on. Death was due not to bacterial action but to the extremely severe irritating effect of the barium on the viscera and the splanchnic nerves. Late roentgenologic examination and histologic studies demonstrated that the barium sulfate was not being absorbed from the peritoneal cavity. The early and late histologic appearances of the liver, spleen, kidneys, stomach, intestine, omentum, mesentery and abdominal wall presented a typical picture of a connective tissue encapsulation process of a nonabsorbable foreign body. The process was limited to the superficial broad surfaces of the viscera. The parenchyma did not present any pathologic alterations in late studies. The author makes the following therapeutic suggestions: (1) thorough removal of the still nonadherent barium sulfate in the course of operation, (2) simple suture of the perforation in the presence of a considerable escape of the contrast material into the free peritoneal cavity and (3) prophylactic support of the peripheral circulation.

\*Further Cases of Pelger's Nuclear Anomaly. M. Alieff and R. Reekers.—p. 1522.

**Treatment of Diphtheria with Cevitamic Acid.**—Otto cites observations on the relations between diphtheria and the vitamin C reserves of the organism. He was induced to use cevitamic acid as an adjuvant in the treatment of diphtheria by the observation that patients with diphtheria eliminated extremely small amounts of vitamin C in the urine; that is, the administered vitamin C was retained and utilized by the organism that was under the influence of the diphtheria toxin. The retention was especially great when in cases of toxic diphtheria from 500 to 700 mg. of cevitamic acid was administered daily by intravenous injection. To obtain reliable information about the efficacy of cevitamic acid in diphtheria, the author made comparative studies in ninety-two cases treated from Jan. 1 to June 1, 1936. The treatment with diphtheria serum was the same in all cases, but forty-two were treated with cevitamic acid and fifty were not. Tabular reports indicate that the administration of the cevitamic acid made no difference as regards the time of disappearance of the diphtheric membrane and of the temperature, nor did it influence the number of complications and of fatalities. However, the author did observe that the cevitamic acid exerted a favorable influence on hemorrhages, particularly nosebleeds. This he ascribes to the fact that cevitamic acid reduces the permeability of the vessels, as is known also from its effect in essential thrombo-

penia and other forms of hemorrhagic diathesis. The author concludes that, if the retention of large amounts of cevitic acid by diphtheria patients is interpreted as indicating a deficiency of the organism in this substance, its administration is justified up to the time of the disappearance of the membrane and particularly during the development of complications. However, a definite therapeutic value can be ascribed to it only in cases of diphtheric hemorrhages.

**Pelger's Nuclear Anomaly.**—Alieff and Reekers direct attention to the fact that Pelger in 1930 described two cases with a peculiar white blood picture. 1. There was a considerable shifting to the left and there were more staff cells than segmented cells. 2. The staff cells were all of uniform shape: regular forms, usually with a small curvature in the middle of one side. 3. The cells with the segmented nuclei showed a peculiar behavior. They consisted of two fragments that were connected by a thin thread. This behavior was noticeable in the neutrophil as well as in the eosinophil and basophil leukocytes. After citing several other investigators who observed cases with this form of nuclear anomaly, the authors state that they observed it in a patient with lupus of the face. All the members of this woman's family were examined and the anomaly was detected in thirteen persons, belonging to three generations. In discussing the genesis of this anomaly, the authors point out that opinions are still divided as to whether it is a purely constitutional anomaly or whether this blood picture occurs only in tuberculosis. Pelger himself assumed that this blood picture had a relationship with a clinically obscure tuberculosis. Another investigator considers this nuclear anomaly of a purely constitutional nature. However, the authors point out that the family anamnesis of the case analyzed by that investigator shows tuberculosis. That investigator assumed a transmission from the mother to the children, whereas other observers were able to trace transmission from the father. After citing several other opinions, the authors state that in the family studied by them there was considerable tuberculosis.

- \*Prodromal Angina in Measles. B. Dragišić.—p. 1498.
- Symptomatology and Therapy of Thallium Poisoning. M. Heiman.—p. 1500.

**Hormone Regulation of Mammary Glands.**—Herold shows that during pregnancy the combined influence of the estrogenic and corpus luteum hormones prepare the mammary gland for lactation. However, these two hormones have merely a growth-promoting but not a lactogenic action. The building up of the mammary gland not only is the prerequisite for the elicitation of the milk secretion but also provides the basis for influencing the milk secretion by hormone action. Lactation is brought on by the action of the lactation hormone of the anterior lobe of the hypophysis. The author assumes that the expulsion of the fetus and of the placenta removes a blocking mechanism from the hypophysis so that the lactation hormone can be secreted. The blockage is produced by the hormones of the ovary, which, during pregnancy, are secreted by the placenta. The detection and purification of the lactation hormone makes it possible to modify the milk secretion by hormone action. Attempts have already been made to stimulate inadequate milk secretion by the administration of lactation hormone, but, although the results were encouraging, the limited hormone supply still restricts this form of therapy. Moreover, the inhibition of lactation, which thus far has been proved only in animal experiments, may eventually prove valuable in the suppression of undesired lactation, for instance in cases in which the fetus is not viable.

**Prodromal Angina in Measles.**—Dragišić cites reports from the literature and his own observations to demonstrate that the incubation period of measles is not as deficient in symptoms as is widely believed. In a children's clinic he had the opportunity to observe the period of incubation. In a considerable number of cases he observed an initial fever (twenty-

four or forty-eight hours after the infection). This fever subsides, but a tonsillitis may develop either from eight to ten days before the development of the exanthem or, more often, from three to four days before. In the forty cases observed by the author, the tonsillitis was usually of the follicular type. In discussing the significance of the tonsillitis that occurs during the incubation period of measles the author states that it is not advisable to base the diagnosis of measles on it exclusively. Only if the epidemiologic conditions are known (in families, children's clinics and so on) may the premonitory tonsillitis be regarded as an indication of the approach of measles.

- \*Bursitis Calcanea in Skaters. H. Kraus.—p. 1340.
- Chronic Ulcerating Colitis in Thrombopenia: Case. A. Czabafy.—p. 1343.

**Pancreatohepatic Syndrome.**—Edelmann observed a number of patients with pancreatic disturbances in whom neurologic and dermatologic symptoms predominated. He reports one case that was under observation for months. The patient had abdominal symptoms that gave the impression of a cholecystopathy. A surgical intervention revealed a normal gallbladder, but the pancreas showed signs of chronic pancreatitis. The patient also developed a number of neurologic and psychiatric symptoms which indicated the presence of multiple foci (caused by toxins or ferments) in the brain and spinal cord. Moreover, a polyneuritis indicated involvement of the peripheral nerves. Then there were psychic disturbances of the type of Korsakoff's syndrome, and the examination of the vestibular apparatus disclosed a number of disturbances, such as failure to respond to caloric stimulation, attacks of vertigo, and disturbances in the equilibrium. The patient became extremely emaciated and he also had cutaneous disorders in the form of atrophy, diffuse gray pigmentation and follicular hyperkeratosis. In discussing this case the author emphasizes the necessity of differentiating between acute pancreatitis, with its fulminant manifestations and usually fatal outcome, and the chronic form in which the pancreatic juice may enter the blood stream, just as bile may enter the blood stream in case of disorders of the biliary system. Whether the pancreatic juice that enters the blood stream injures the central nervous system directly or by way of other organs, the author is unable to say; at any rate there seems to be a neurotropic and dermatotropic tendency. The author describes other cases of chronic pancreatitis and shows that in some of them the described syndrome is amenable to therapy; for instance, in cases of obstruction or stenosis of the pancreatic duct or in cases in which, as the result of pancreatic swelling after gastric or duodenal ulcer, a lymphangitis develops in the region of the head of the pancreas. He concludes that a knowledge of the syndrome here described has repeatedly proved helpful in the diagnosis of chronic pancreatic disturbances. Moreover, the passage of pancreatic juice into the blood stream may play a part in the pathogenesis of various syndromes of the central and peripheral nervous system.

**Bursitis Calcanea in Skaters.**—Kraus directs attention to a disorder that he observed in skaters, which could be traced to faulty shoes. It consists of a subcutaneous bursa on the calcaneus which develops as the result of pressure from the too greatly curved and stiffened heel portion of the skating shoe. The first symptoms usually appear shortly after new shoes have been used. Pains develop on the calcaneus, particularly at the attachment of the triceps surae. Examination reveals a pressure point on the calcaneus and in the later stages reddening and swelling of the skin in the painful area. In contradistinction to bursitis of the achilles tendon, the tendon is not painful. One of the chief factors in the therapy is the altering of the skating shoe. The stiffened and curved heel portion is removed and is replaced by a strip of soft leather 3 cm. in width. The painful area on the foot is protected by an adhesive bandage. After three or four days the patients are usually able to skate again.

**Sovetskiy Vrachebnyy Zhurnal, Leningrad**

October 30, 1936 (No. 20) Pp. 1521-1600. Partial Index

- Washing Out of Stomach and Duodenum as Therapeutic Method. N. A. Bukatko.—p. 1530.

- Scarlatinal Otitis in Young Children. A. I. Ivanova.—p. 1559.

**Short Wave Therapy.**—According to Piontkovskiy and Fabricant, short wave therapy markedly altered the clinical course of acute local suppurative processes, such as furuncles, carbuncles, adenitis, phlegmons, panaritiums and mastitis. The most striking effect noted was the total disappearance or marked diminution of pain. The analgesic effect appeared to be superior to any obtained by physical therapeutic measures. There was rapid disappearance of the edema of the tissues surrounding the inflammatory focus and of the redness and immobility of the part involved. The treatments were followed as a rule by a fall in body temperature. The effect on the lesion was to accelerate the process of suppuration and absorption. One or two treatments frequently led to spontaneous opening and copious discharge of pus followed by rapid healing. Early application of short wave therapy frequently resulted in aborting the inflammatory process. The authors obtained their best results in cases of furuncles and carbuncles. Panaritiums and lymphadenitis required longer treatment, while the results in mastitis were negligible. All cases of phlegmon of the hand required surgical intervention. The authors warn against the use of a strong current in these cases, for fear that the heat created in the tissues may cause the inflammatory process to spread. The therapeutic effect of short waves did not seem to depend on the creation of heat within the tissues, since identical results are obtained with small doses incapable of producing the sensation of warmth. The authors likewise could not confirm the alleged bactericidal effect of the waves in their experiments in vitro. Observations on cultures of *Staphylococcus pyogenes-aureus*, *Bacillus typhi-abdominalis* and *Bacillus subtilis* failed to show any such effect. Smears and cultures from pus of carbuncles treated with short waves failed to demonstrate a bactericidal effect in spite of a favorable clinical course. The authors suppose that the favorable effect was due to the action of the waves on the host rather than on the microorganisms. The results in seventeen cases of chronic osteomyelitis were negligible. Of eleven patients suffering from polyarthritis, ten did not obtain any benefit from the treatment. As to the hazards of short wave therapy, the authors point out that, while it may be considered entirely safe in the hands of a trained physical therapist, the possibilities of a burn are greater than with diathermy.

**Umbilical-Placental Blood for Massive Transfusions.**

—Because of a demand for blood transfusions in the surgical treatment of malignant neoplasms, Bruskin and Farberova of the Central Oncologic Institute of Moscow resorted to the use of blood obtained from the umbilical vein and the placenta of the new-born. They believe that fetal blood is particularly valuable because of its high immunobiologic antitlastic quality against neoplasms. The amount obtainable from one placenta varies between 50 and 120 cc. Bruskin demonstrated in dogs the safety of utilizing blood from several donors. The authors proved in their clinical work the safety of using a mixture of blood from several donors of the same group. In the last four months, 114 transfusions of umbilical-placental blood were performed at the institute and sixty at the lying-in hospital. Studies of the morphology and of the biochemical properties of placental blood demonstrated the high content of the important elements. The hemoglobin was found to vary from 90 to 120 per cent, red cells from 5,000,000 to 6,000,000, and leukocytes from 8,000 to 16,000 with a definite lymphocytosis (32 to 46 per cent). The reticulocytes varied from eleven to thirty in 1,000 cells. A number of authors believe that placental blood contains a number of hormones of ovarian and anterior pituitary origin. The blood was conserved for from six to ten days. The authors estimate that, of the 60,000 annual births in Moscow, 40,000 could be used for the purpose of collecting placental blood. An average of 50 cc. from each birth would yield 2,000 liters, or an amount sufficient for from 6,000 to 8,000 blood transfusions.

**Norsk Magasin for Lægevidenskapen, Oslo**

97: 1001-1112 (Oct.) 1936

- \*Angina Pectoris: Contribution to Illumination of Pathogenesis and Anatomic Basis. A. Jervell.—p. 1001.

- Shoulder Delivery in Breech Presentation and New Method of Performing It. J. Løyset.—p. 1041.
- Retrograde Pyelography in Upright Position. J. Stang.—p. 1049.

**Angina Pectoris.**—From his investigations, Jervell concludes that angina pectoris pain of the type of effort angina and the so-called status anginosus in cardiac infarct are closely related clinically and pathogenically. In status anginosus the basis is an absolute coronary insufficiency in a limited field, corresponding to acute coronary stenosis; in effort angina it is a relative coronary insufficiency manifested only under special conditions, as in physical exertion, the anatomic cause most often being a coronary stenosis. In both, only anatomic changes in the great coronary branches are to be considered. In cases of extensive coronary sclerosis not accompanied by angina pectoris, the blood supply for the entire myocardium is probably insufficient. The heart has to suspend its work after coronary circulation, the contraction ability diminishes, the minute volume becomes inadequate and symptoms of insufficiency appear, first of all dyspnea. There need be no actual ischemia of the myocardium. If, on the contrary, a particular coronary branch is stenosed while the coronary circulation is otherwise satisfactory, the insufficiently nourished part must follow the well nourished heart musculature in its reaction to increased demands. A local ischemia then results, causing symptoms of angina pectoris. This view of the pathogenesis of angina pectoris explains the presence of grave coronary sclerosis without angina pectoris and, conversely, the occurrence of violent attacks without extensive changes. The decisive factor is thus not the extent of the sclerosis but the extent to which it causes stenosis in one of the main branches, leading to a disproportion between the blood supply to the different parts of the heart.

**Incarcerated Diaphragmatic Hernia.**—Røvig describes the case of a woman, aged 38, who was operated on under the diagnosis of volvulus coli. There was an incarcerated diaphragmatic hernia of unusual size with abnormally long colon (macrocolon) as hernial content. He says that hernia and colon malformation were undoubtedly congenital. The hernial portal was a grave defect in the left side of the diaphragm corresponding to the foramen of Bochdalek. A palliative intervention was indicated and after phrenic exeresis on the left side the transverse and descending colon were anastomized subphrenically. On after-examination about two and a half years later the patient had but slight subjective symptoms and was able to work. The roentgenogram showed satisfactory functioning of the anastomosis and, as before, a long colon loop in the left side of the thorax. In a certain reclining position the hernia was complicated by transposition of the stomach, duodenum and small intestine to the left side of the thorax, but spontaneous reposition occurred on shifting the position.

**Amyloid Kidney.**—Opsahl's first patient with subacute anhydropic form ending in uremic coma was a woman, aged 28, with a history of fistulous tuberculous coxitis which had healed with ankylosis and, fifteen years later, a cavernous pulmonary tuberculosis of rapid course. The second and third patients were a man, aged 31, and a woman, aged 36, who had bilateral autochthonous thrombosis of the renal veins without recognized clinical symptoms of a thrombosis. The basic disorder was a cavernous pulmonary tuberculosis with a course of at least two and six years, respectively. The fourth patient, a man, aged 40, who presented the picture of a lipid nephrosis, had histologically diffuse degeneration and atrophy, considerable hypertrophy of the heart and no hypertension, finally hypotension, Addison coloration of the skin and marked amyloid deposits in the adrenal cortex and medulla. The basic disease was a chronic polyarthritis on a gonorrheal basis (without suppuration). The heart atrophy is regarded as the expression of an earlier arterial high tension, probably due to a diffuse glomerulus degeneration in the kidneys. The normal or subnormal pressure in the later course of the disturbance is attributed to adrenal insufficiency.

## THE CLINICAL SIGNIFICANCE OF AURICULAR FIBRILLATION

DREW LUTEN, M.D.

ST. LOUIS  
AND

E. O. JEFFREYS, M.D.

CHICAGO

Some thirty years ago Mackenzie observed that in certain cases of auricular fibrillation a conspicuous reduction of ventricular rate follows the administration of digitalis. Mackenzie believed that the accompanying relief of symptoms probably was to be attributed to the slowing, a conception elaborated and strengthened by Sir Thomas Lewis. Knowing of no beneficial effect of digitalis on the musculature of the failing ventricle, Lewis referred clinical improvement entirely to reduction in rate. The slowing was explained as due to a measure of auriculoventricular block induced by a special action of the drug on the connecting tissues. Since block of moderate extent will slow the ventricle only in cases of auricular fibrillation, this explanation logically limited the use of digitalis to cases of that arrhythmia. Lewis has held, furthermore, that the existence of established fibrillation implies disease of ventricular muscle and that the congestive heart failure which is present in most cases results from the tachycardia of the abnormal rhythm. On these postulates it has regularly been taught that digitalis should be employed to control ventricular rate in auricular fibrillation; if heart failure is present the ventricle will be relieved of the harmful effect of tachycardia and allowed to recuperate; if heart failure has not yet appeared, the block-producing action of the drug will protect the ventricle from rapid beating and thus tend to prevent failure; in all cases the drug should be used.

Under this conception, the significance of auricular fibrillation in any case is quite simple. It embodies merely the obligation properly to administer digitalis. At present, however, many physicians, while adhering to this time honored conception in its essential aspects, still entertain certain notions which in one or another particular are quite at variance with the premises on which it was founded. Interest is being manifested in the question of the cause of the abnormal rhythm as well as in the problem of management. More than once, in recent years, attention has been called to the existence of established fibrillation with neither heart failure nor heart disease. By almost every one it is now agreed that the use of digitalis should not be limited to cases of auricular fibrillation but that regularly in congestive heart failure the drug is of great value because of an effect directly on the muscle of the ventricle—an effect

independent of rate or rhythm. Increasing attention, moreover, is being given to the observation made by Mackenzie that, in certain cases of the arrhythmia, digitalis causes no slowing in rate. There is an increasing tendency to omit the drug in special cases.

We have come to think of auricular fibrillation as follows: In certain situations some unusual factor may act on the wall of the auricle in such a way as to initiate the abnormal movement. It is to the underlying disorder rather than to its manifestation that chief attention must be given in diagnosis and in therapy; digitalis may or may not be indicated. This point of view is not new but it appears not yet to be very generally held. It has been our impression that in fibrillation it is only in cases of congestive heart failure that therapeutic doses of digitalis produce ventricular slowing and that in other cases no occasion exists for employment of the drug.

### OBJECT AND PLAN OF STUDY

In order to check the correctness of this notion, we made a detailed study of the records of the Barnes Hospital. An additional object was to note the clinical conditions associated with the abnormal rhythm, data which might throw light on the problem of etiology.

Beginning with July 1, 1925, 431 consecutive case records of fibrillation were investigated. We recorded the sex, the age, the principal diagnosis, the cardiac diagnosis, the electrocardiographic diagnosis (in addition to that of auricular fibrillation), the presence or absence of any evidence of heart disease, the etiologic type, evidences of specific valvular lesions, the changes found at autopsy with regard to the auricle, the presence or absence of toxic agents and of fever, whether or not the auricular fibrillation stopped, whether or not there was any evidence of heart failure, whether or not digitalis was employed, the amount and period of time of administration, the change in heart (or pulse) rate after digitalis, other cardiac therapy, surgical operations and the hospital "result."

### RESULTS

*Heart Disease.*—In 253 of the cases the principal diagnosis was related to the heart; in 178 cases it was noncardiac. Electrocardiograms were made in 387 cases. In 256 the record was thought to indicate some abnormality other than the arrhythmia, in 131 no other abnormality. Including secondary diagnosis, mention was made of some cardiac abnormality in addition to auricular fibrillation in 375 cases. In the remaining fifty-six cases no cardiac diagnosis was recorded, but study of these records showed that in fourteen some cardiac disorder might possibly have been suspected. Excluding these cases of "possible heart disease" there were left forty-two cases in which there existed no suspicion of anything wrong with the heart other than the auricular fibrillation itself. Examples of such cases are splenic anemia, fracture of the skull, carcinoma of

the uterus, carcinoma of the mouth, carcinoma of the cervix, ureteral colic, strangulated hernia, embolism of the pulmonary artery, and neuralgia of the fifth cranial nerve.

*Type of Heart Disease.*—There were the following diagnoses of heart disease: rheumatic, 136; "arteriosclerotic," 114; hypertensive, 55; thyroid, 57; syphilitic, 7; miscellaneous, 6; no cardiac diagnosis, 56. As just stated, this group of fifty-six cases presenting "no heart disease" was further reduced to forty-two by exclusion of certain cases in which it appeared possible that minor degrees of heart disease might have escaped attention.

*Valvular Lesions.*—In many instances, diagnosis of more than one valve lesion was recorded. The following enumeration was made: mitral stenosis, 119; mitral insufficiency, 127; aortic stenosis, 21; aortic insufficiency, 30; tricuspid stenosis (autopsy confirmation), 1; tricuspid insufficiency, 6. The total number of cases presenting a valve lesion amounted to 230, and the total number of cases without evidence of valve lesion was 201.

*Heart Failure.*—All cases with a recorded diagnosis of heart failure were segregated. To this group were added all records which gave any evidence that some degree of heart failure might possibly have existed. There were 334 cases in this "heart failure" group, leaving ninety-seven cases in the non-heart failure group. Division was made on this basis with the particular object of studying the effect of digitalis in the absence of congestive heart failure, care being taken to exclude questionable cases. It is possible, therefore, that the actual number of cases of failure may have been somewhat less than 334.

*Sex and Age.*—There were 220 males and 211 females in the series. Ten patients were under 20 years of age, seventy under 40, and 150 under 50; 281 patients were 50 years of age or more and 167 were 60 or more. Fifty-five patients were as old as 70.

*Autopsy.*—Autopsy records were included in sixty-eight case histories. Most of them unfortunately followed the usual rule of centering attention on the ventricle, but in eighteen cases it is noteworthy that data were recorded relating to the auricle. The predominant changes were scarring, fibrosis, mural thrombi (some organized) and dilatation.

*Toxemia and Fever.*—In 280 cases there was evidence of toxemia or fever, or both.

*Nervous Factors.*—In a certain number of cases the chief if not the sole factor in the cause of the abnormal rhythm appeared to be of reflex nervous origin. Examples are neuralgia of the fifth cranial nerve, ureteral colic, thrombosis of the lenticular striate artery, and fracture of the skull.

*Cessation of Auricular Fibrillation.*—There were fifty-four cases in which the arrhythmia ceased either temporarily or for the remainder of the patient's hospital residence, in some of which it had begun after admission. Thirty-three were in patients with heart disease, twenty-one in the group without heart disease. These temporary cases were divided roughly into the following subgroups: (a) Recurrent or intermittent cases with so-called spontaneous cessation in which the exact causes of the cessation of the arrhythmia could not be determined. (b) Cessation with quinidine. This group cannot be divided sharply from the preceding group. (c) Cases in which the arrhythmia occurred with a known excitant and ceased with subsidence of

its effect. Examples are onset after administration of vaccine, insulin or digitalis; with an anesthetic, and after operation. In this group should be included those cases of thyrotoxicosis in which the fibrillation stopped after thyroidectomy and perhaps such cases as pneumonia and other intoxications with temporary auricular fibrillation. (d) A few cases of heart failure of moderate degree in which the abnormal rhythm stopped after improvement with digitalis.

*Surgical Operations.*—Operation was performed in forty-eight cases in which auricular fibrillation was present before and at the time of operation. There were two deaths, both after operation. In neither case was there evidence that the auricular disorder was in any way responsible for the fatal outcome, one patient dying of hemorrhage and the other of pneumonia.

*Digitalis.*—Digitalis was administered in 341 cases and was not given in ninety. Taken as a whole, the series, covering a period of about ten years, gives evidence of no consistent policy for determining whether or not to administer the drug in cases of auricular fibrillation. It does show, however, that the proportion of all cases in which digitalis was given was higher in the earlier years, while as time went by there was an increase in the proportion of cases in which the drug was withheld. This applies particularly to cases in which there was no evidence of congestive heart failure. This tendency to give digitalis less regularly in cases of the arrhythmia without heart failure shows that among the staff members auricular fibrillation per se came less and less to be regarded as a specific indication for digitalis but that in cases of auricular fibrillation digitalis administration came more and more to depend on the general indication of congestive heart failure. In certain cases in spite of heart failure digitalis was regarded as contraindicated. In some there had been overdigitalization, in others thyrotoxicosis or other toxemia or some such attendant circumstance as coronary thrombosis was given as the reason for withholding the drug. In still other cases with a recorded diagnosis of heart failure no reason for withholding the drug was given, the physician apparently not having been impressed with any data which might have caused the diagnosis of failure to be entered on the record. All in all, of the ninety instances of auricular fibrillation in which digitalis was not administered, forty were cases of heart failure (or possible heart failure) and fifty were in the non-heart failure group (no suspicion of heart failure).

With the administration of digitalis in cases of heart failure, whether accompanied by auricular fibrillation or not, this study is not concerned. There is general agreement that, except for unusual circumstances, patients with congestive failure accompanied by auricular fibrillation should receive the drug. Authorities almost without exception now agree that other patients with heart failure also should get it. With regard to the indication for digitalis in cases of auricular fibrillation without congestive failure, however, disagreement in opinion if not in practice still exists. It was to the effects of the drug in such cases in this series that our attention was particularly directed.

*Effects of Digitalis in Non-Heart Failure Cases.*—Of the ninety-seven cases without suspicion of congestive heart failure, digitalis was administered in forty-seven and not given in fifty.

In the no-digitalis group were twelve cases of thyroid disease, four of carcinoma, two of cataract, two of hernia, and one each of enlargement of the prostate,

fracture of the skull, diabetes, urticaria, acute yellow atrophy of the liver, neuralgia of the fifth nerve, after vaccine administration, cholecystitis and pulmonary embolism. Twelve cases were listed as "not treated," twenty-eight as "improved," six as "not improved." There were four deaths.

In the digitalis group were seven cases of pneumonia, seven of thyroid disease, four of carcinoma, two of cholecystitis, two of enlargement of the prostate, one each of tabes, mesenteric thrombosis, after insulin administration, cataract, strangulated hernia, fracture of the femur, and tuberculosis of the vertebra. The hospital results showed twenty-eight as "improved," six as "not improved." There were thirteen deaths.

Although the mortality was higher in the digitalis group, it might be argued that this group contained a larger number of extremely ill patients, a postulate difficult of refutation or of substantiation. In at least one instance of intravenous administration death was attributed by the physician to digitalis. In most of the other cases there was little direct evidence that the drug did harm, but neither was there any evidence of any beneficial effect. In none of these cases without heart failure did the record give evidence of any slowing effect on the ventricular rate. In three of the fatal cases there was an acceleration after digitalis. In one (carcinoma of the cecum), 18 cc. of the tincture was administered the day before death; in another (strangulated hernia), 12 cc. of an intravenous preparation administered in twelve hours was followed by 0.1 Gm. daily; in the third (postoperative pneumonia), 1.2 Gm. was given in twelve hours.

#### INTERPRETATION OF RESULTS

Whatever the ultimate factors, it is obvious that the immediate causes of the abnormal auricular movement must be applied to the wall of the auricle, acting on the muscle or nerves (or both). It appears that in most cases heart disease is an important factor, whether its effects are directly or indirectly applied to the auricular wall. That organic heart disease is not necessary to the occurrence of fibrillation is indicated by the fact that it was not present in about 10 per cent of the cases. This occurrence of auricular fibrillation in patients without heart disease is in accord with the recent studies of Fowler and Baldrige,<sup>1</sup> Friedlander and Levine,<sup>2</sup> Orgain and White,<sup>3</sup> and others. While in most cases some pathologic process of the auricular muscle doubtless is an important factor, minor lesions appear to suffice in many instances, and in others nervous factors alone. It has been explained as "the result of a 'trigger phenomenon' of neurogenic origin in many cases."<sup>2</sup> In one of our cases of recurrent fibrillation the patient stated that emotional excitement frequently caused a paroxysm. This is in accord with the long recognized influence of nervous effects as well as direct muscular factors on the production of the circulating wave in the auricle of experimental animals. Certainly the auricular arrhythmia per se can no longer be regarded as implying disease of the ventricle.

Analysis of these cases strongly suggests that, while reflex nervous influences and toxic agents often may be

causative factors, the chief agent in the initiation of the abnormal rhythm in most instances is increase in intra-auricular pressure. The well recognized association of the arrhythmia with mitral valve disease and with congestive heart failure is conspicuous in this series. In explaining the association of fibrillation with mitral stenosis, the valve lesion usually has been regarded as in some way a contributory cause of the arrhythmia, while in explaining the common association of the disorder with congestive heart failure it has been assumed that the arrhythmia is the cause of the failure. Not only does this explanation of heart failure ignore the presence in these cases of such common etiologic factors as infection, strain and diminished blood supply—factors now regarded as prominent causes of failure—but it involves further fallacy. The mere association of two observed phenomena can give no implication of cause and effect in one direction more than in the other, unless supported by collateral evidence. The accumulated evidence indicates that congestive failure as well as mitral disease promotes the initiation of auricular fibrillation. Both tend to increase intra-auricular pressure. Such increase in pressure is known to cause auricular fibrillation in heart-lung preparations<sup>4</sup> and has long been implicated in the clinical<sup>5</sup> explanation of the disordered rhythm.

In this conspicuous association of auricular fibrillation with congestive heart failure we are aware of the impossibility of differentiating cause from effect, a difficulty which appears sometimes not to have been appreciated. In patients who first come under observation with congestive heart failure and auricular fibrillation, it usually is impossible to determine which of the two phenomena was first to occur; but on the basis of experimental and clinical evidence it would appear far more logical to explain the arrhythmia as resulting in part from the increase in intra-auricular pressure attendant on congestive failure than to explain the failure as a result of the abnormal auricular movement. In many patients who have been observed over a period of years, failure is known to antedate the onset of auricular fibrillation. It appears to be the precipitating factor in the initiation of the arrhythmia. In many patients with few evidences of congestive failure it may be the arrhythmia which first attracts attention. In some such instances of early failure the onset of auricular fibrillation may indeed have been a blessing in that it has pointed the way to proper, even if misdirected, therapy. In a recent study of great merit Nahum and Hoff<sup>6</sup> call attention to stretching of the auricle from the pressure of congestive failure as a precipitating cause of auricular fibrillation. They say: "It thus becomes clear why this irregularity is so often associated with heart failure, being rightly regarded as an important evidence of the existence of heart failure." Stoppage of the abnormal rhythm after digitalis in a few of our cases with moderate heart failure suggests that the crucial factor in the restoration of normal rhythm may have been a decrease in intra-auricular pressure consequent on improvement in the circulation from the drug.

Stretching of the auricle alone, however, whether from ventricular failure or from mitral stenosis, usually does not suffice to cause clinical auricular fibril-

lation. As a rule it is effective only in cases in which it appears that certain changes have occurred in the auricular wall. The relative rarity of the arrhythmia in children is well recognized even though in them rheumatic heart disease predominates. In our series the association of auricular fibrillation with older age indicates that changes such as are incident to advancing years constitute an important contributory factor. The autopsy reports give the same implication. In view of the great effect of digitalis on ventricular rate in heart failure cases of auricular fibrillation, the failure of the drug to produce slowing in the non-heart failure cases is highly significant. It appears that slowing is related to its beneficial action on the muscle<sup>7</sup> in heart failure—an action whereby the heightened irritability of the musculature is reduced.<sup>8</sup> But it is only on the failing ventricle that digitalis lessens excitability. In toxic cases without failure it may even make the muscle more irritable.

## SUMMARY

Auricular fibrillation may result from various influences acting on the muscle or nerves of the auricle. In some cases muscular effects are chiefly if not wholly responsible; in others nervous factors, direct or reflex, constitute the sole or predominating influence. Ultimate causes include toxemia; various nerve reflexes, central, abdominal, peripheral; nervous or emotional stress; lesions of the auricular musculature, and increased intra-auricular pressure. This study of 431 consecutive cases suggests that the commonest determining factor is increase in intra-auricular pressure from congestive heart failure or from mitral disease, exerted on the wall of an auricle which is the seat of changes such as occur with older age. Congestive heart failure is the commonest cause of auricular fibrillation.

Auricular fibrillation calls for examination. Search should be made for other evidences of toxic or nervous disorder and for other signs of heart failure. In a certain number of older patients the abnormal rhythm may be the first sign of congestive failure to attract attention, and in such instances obviously digitalis is indicated, as in other cases of heart failure. If exact etiologic diagnosis is obscure it may become appropriate to administer digitalis as a therapeutic test, but such experimental administration should no more be confused with specific therapy than should the administration of quinine in cases of unexplained fever. Seldom if ever is auricular fibrillation *per se* an indication for digitalis.

In non-heart failure cases of the arrhythmia, the administration of therapeutic doses of digitalis produces no slowing of ventricular rate. In a few such cases in this series, digitalis intoxication of greater or less degree was induced, a danger which appears not to be inconsequential if the drug is used in any attempt to slow the rate in toxic cases.

Auricular fibrillation is a result, not a cause, of some disorder that may need treatment. In cases of congestive heart failure with fibrillation the heart failure should be treated as in other cases of failure—with digitalis. In toxic or nervous disorders with the arrhythmia, treatment likewise should be the same as in similar cases with normal rhythm, thyroid disease should receive appropriate therapy, toxemia should be combated, nervous factors allayed. In both classes of cases (with and without heart failure), auricular fibrillation is a sign in diagnosis, not a disease *per se*.

Occasionally the cause of the arrhythmia cannot be found or controlled, and the symptoms may be so prominent as to call for special therapy. In many such instances the disorder may be obliterated with quinidine.

It is no more correct to administer digitalis regularly on all occasions of fibrillation than it is to perform thyroidectomy, although each procedure is helpful in appropriate cases. A standard pattern of treatment is no more applicable in auricular fibrillation than in enlargement of the liver, in chills, in simple tachycardia or in edema. It is not to the sign but to the disease which produces it that treatment must be directed.

IMMUNITY AND PROPHYLAXIS IN  
POLIOMYELITIS

E. W. SCHULTZ, M.D.

STANFORD UNIVERSITY, CALIF.

It is generally known that poliomyelitis virus possesses a high degree of host specificity, man alone being susceptible to natural infection. With the exception of certain Old World species of monkeys, lower animals of all kinds are refractory to it. Even those species of monkeys which yield to experimental inoculation never contract the disease spontaneously from infected associates. They also are therefore endowed with a fair degree of natural resistance, differing from the natural state in man in that quite artificial conditions must be imposed to induce infection. This difference in susceptibility, incidentally, must be borne in mind in the application of experimental results to man.

The resistance exhibited by naturally refractory animals does not appear to be related to humoral antibodies, for the serum from such animals rarely inactivates the virus *in vitro* even when a high ratio of serum to virus is employed. On the contrary, it appears to rest largely or wholly on tissue resistance, possibly simply on an indifference on the part of the nerve cells to the presence of the virus.

In those animals which yield to experimental inoculation, marked individual differences in resistance may be recognized. This individuality may be elicited by the use of graded doses of virus and by noting differences in the extent of the paralysis in animals inoculated with the same dose of virus. Epidemiologic and clinical observations suggest that marked individual differences in native resistance exist in man also. There is indeed some justification for believing that an important factor in determining the outcome of an exposure to infection in man is the general level of tissue resistance with which the individual has been naturally endowed, frank paralytic poliomyelitis probably being restricted largely to those members of society whose nerve cells, genetically speaking, are constitutionally inferior so far as resistance to this particular virus is concerned. This is in a measure reflected by the fact that approximately three fourths of normal young adults in urban communities exhibit indirect evidence of naturally acquired active immunity, though it must be admitted that a demonstration of neutralizing properties in the serum of persons not giving a history of the disease does not necessarily mean that these individuals have really acquired actual immunity to the disease as the result of contact with virus. The exceedingly variable clinical course in those who do develop frank poliomyelitis may

Read before the second International Congress for Microbiology, London, July 31, 1936.

be regarded as further evidence of individual differences in susceptibility to this disease, the more vulnerable individuals apparently being the exception rather than the rule.

While it is a well established fact that naturally acquired active immunity to this disease is commonly associated with humoral antibodies, it is not evident that these play a significant rôle in determining recovery or that they figure largely in the refractory state which follows recovery. Recent investigations have in fact shown quite conclusively that immune serum, even when administered to monkeys in very large doses, does not afford significant protection against virus inoculated by the intranasal route. This failure of the humoral factor to rally to the defense of the body may be explained by the fact that the virus normally gains admission to the central nervous system by the olfactory nerves, the terminals of which lie free on the nasal mucosa and therefore probably are largely or entirely unguarded by humoral antibodies. Once the virus has become established within this portal, it continues to be largely out of the reach of humoral antibodies. This is evidenced by the fact that a very large dose of highly active immune serum administered as early as two days after intranasal inoculation does not in any way alter the course of an experimental infection. It is now known that the virus is a strict neurotrope which travels from one level of the nervous system to another largely or entirely by axonal paths, probably inside neurons and therefore essentially out of the reach of circulating antibodies. Such limited protection as immune serum may afford against subsequent experimental inoculation by the intranasal route (in my experience less than 25 per cent) may be accounted for in part by the fact that the technic of infecting monkeys by this route may result in a local inflammatory response, with possibly sufficient exudation of the immune serum injected to inactivate virus adhering to the mucous surface and furthermore by the fact that monkeys are, in comparison with man, fairly resistant to infection by this route. Since inflammatory exudation is normally not apt to aid man at the time of exposure and since he is more susceptible to natural infection than monkeys, it would appear that humoral antibodies must play little or no rôle in human resistance to this disease.

What significance then is attached to the humoral antibodies which are so commonly associated with naturally acquired active immunity? While the answer is still not entirely clear, there are rather definite indications that they represent merely an adventitious by-product of infection; a general response to virus which has escaped from infected neurons, whether these have been damaged or not, and that the real basis of the immunity which follows infection is not humoral in nature but rests very largely or entirely on a cytoplasmic modification of previously susceptible neurons. In other words, the humoral antibodies are to be looked on as a reflection of the fact that the nerve cells have actually been exposed to the modifying influence of virus, for the modification, whatever its exact nature may be, seems to depend on intimate contact of the neurons with the causal agent. This cytoplasmic modification may not be at all associated with the formation of antistances but consists rather of the acquirement of new properties which leave the cells indifferent to the presence of this virus—traces of which may indeed persist for a time in the tissues, as seems to be true in certain other virus diseases.

A clear recognition of these relationships is obviously necessary for an understanding of the problem of creating resistance by artificial means. It is now known that passive immunization is not very effective against infection by the natural route; also that, while some increase in resistance may be brought about by the repeated injection of large doses of active virus over a sufficiently long period, the response to such injections seems to be largely, if not entirely, humoral in nature and is not associated with a significant increase in tissue resistance. What is of great practical importance is that, when the virus has been inactivated by physical or chemical means to make it safe as a vaccine, even the humoral response tends to drop out of the picture.

In the light of these facts the practical problem of creating resistance by artificial means assumes discouraging dimensions. Enough is now known about the pathogenesis and basis of immunity in this disease to justify considerable doubt that its control will ever be solved by means of serums or vaccines. It seems clear that a solution must be sought in new directions and the possibility that a practical solution may lie in a less orthodox direction does not seem entirely out of consideration. Indeed, a new hope has emerged from recent observations by Armstrong and Harrison,<sup>1</sup> Olitsky and his associates<sup>2</sup> and Gebhardt and myself,<sup>3</sup> which indicate that certain essentially harmless chemical agents once thoroughly applied to the olfactory mucosa of monkeys may afford protection against the virus for several weeks to several months thereafter. The substances which fall into this category are varied in composition and include alum, tannic acid, trinitrophenol (picric acid), zinc sulfate<sup>4</sup> and certain dyestuffs. Their modes of action may differ, but the protective effect is nevertheless exhibited in varying degrees by a number of these agents. It is already known that certain ones, once thoroughly applied, may provide protection for as long as three months. Since the protection may last for some weeks, it appears that the effect which they produce is not due to a virucidal action but depends on some modification in permeability of the normal portal of entry. Though by no means fleeting, the effect is temporary, since most animals do succumb in time to repeated intranasal instillation of virus.

From the general facts brought into this review, it seems clear that the trend of future investigations, so far as they relate to personal prophylaxis, should and very likely will center around means of guarding the olfactory area against the establishment of the virus at this point. Since certain chemical agents have already been found to exercise protective action in monkeys, further investigations along this line are clearly indicated. More work needs to be done in an effort to elicit the most satisfactory agent for human application, to determine precisely how the various chemoprophylactic agents act, and to determine the duration of the

Biol. & Med.* 34: 133-135 (March) 1936; Chemoprophylaxis of Poliomyelitis, *California & West. Med.* 45: 138-140 (Aug.) 1936.

4. Observations since this paper was read in London indicate that zinc sulfate (from 0.5 to 1 per cent) is the most effective of the agents we have studied thus far; about 95 per cent of a total of fifty-three monkeys have resisted virus inoculated intranasally as long as a month after treatment of the nasal mucosa with this chemical, while about 95 per cent of an almost equal number of untreated controls developed the disease.

protection each affords, together with any harmful effects they may have on the tissues of the individual so protected, which would contraindicate their use. It must, of course, be borne in mind that results obtained in experimental animals are not always directly applicable to man.

While the use of chemical agents in this way may have application against diseases other than poliomyelitis, the possibility should be borne in mind that an agent which is effective in protecting against one virus disease may not necessarily be effective in protecting against another, even though the portal of entry may be the same. This much has already come out of comparative studies on poliomyelitis and St. Louis encephalitis, it being more difficult experimentally to protect against the latter than against the former disease.

That there may not be undue confusion later, it will be important for investigators to compare their observations with reference to a given disease, and certainly important to compare their results in terms of the procedures employed. There must, of course, be no uncertainty as to making good contact with the actual portal of entry, and such factors as the concentration of the agent, the nature of the menstruum, the temperature of the solution at the time of application, the number of applications and the interval between applications will all require careful attention and should be given in detail in publishing observations. It is to be hoped that, with the passage of time, chemoprophylaxis may come to be regarded as an effective aid in the control of this and possibly other virus diseases.

## THE CLINICAL USE AND DANGERS OF HYPNOTICS

SOMA WEISS, M.D.  
BOSTON

The administration of hypnotics and of sedatives acting on the nervous system represents one of the most frequently used therapeutic procedures in medicine. Millions are spent for the purchase of these drugs and, as the result of popular interest, they are often used without medical supervision. Indeed, their consumption is so widespread that the question has been raised whether they may exert a deleterious effect on an appreciable proportion of the population.<sup>1</sup> In spite of the fact that these substances represent symptomatic remedies of great value, their use is not without danger. When they are administered intelligently, however, and with full knowledge of their pharmacologic and toxicologic properties, their beneficial effects distinctly outweigh the occasional untoward reactions. Instances are also not wanting in which the skilful application of these drugs has saved the patient's life.

There are few questions that recur in the minds of physicians as frequently as the following ones: When and how should hypnotics be used? What are their relative merits and contraindications? How long should their use be continued? How large a dose is it safe to administer? When should they be given by mouth and when parenterally? Will the patient develop a "habit"?

From the Thorndike Memorial Laboratory, Second and Fourth Medical Services (Harvard), Boston City Hospital, and the Department of Medicine, Harvard Medical School.

Read before the joint meeting of the Section on Practice of Medicine and the Section on Pharmacology and Therapeutics at the Eighty-Seventh Annual Session of the American Medical Association, Kansas City, Mo., May 14, 1936.

1. Mörechen, F.: Die Schlafmittelfrage, *Deutsche med. Wchnschr.* 60: 798 (May 25) 1934. Flury, F.: Schlafmittelmissbrauch, *ibid.* 60: 1155 (Aug. 3) 1934.

from their use? What is their effect on the heart and circulation? Is the sudden change in the condition of the patient following the administration of hypnotics due to the hypnotics or is it independent of them? Answers to these questions can be supplied only (1) through the appreciation of certain general established principles, (2) through specific knowledge bearing on the individual drug and (3) through full understanding of the patient as a psychophysical unit.

My purpose in this presentation is to discuss certain general principles bearing on the use of hypnotics. No attempt is made to describe the pharmacologic and therapeutic properties of individual drugs, as this has been done elsewhere.<sup>2</sup>

### RELATION OF HYPNOTICS TO SEDATIVES, ANALGESICS AND ANESTHETICS

Hypnotics are drugs that induce sleep. Sedatives and analgesics are chemical agents that are supposed to decrease the sensitivity of the central nervous system and diminish or abolish pain. Anesthetics, or narcotics, in the strict sense of the word, are substances that depress the central nervous system, abolishing certain types of sensations. Such a classification, however, is quite arbitrary and unsatisfactory from a clinical point of view because the same drug in varying dosage is used as an analgesic, a hypnotic or an anesthetic. Furthermore, if sleeplessness is caused by pain, an analgesic becomes a hypnotic, and, contrariwise, true hypnotics may act indirectly as anodynes. Finally, some hypnotics, such as tribrom-ethanol, are often used as anesthetics. Hence, sharp separation between these types of drugs, so far as effect is concerned, is not feasible. From a clinical point of view, all drugs that can be administered without unpleasant side action and that decrease the sensitivity of the central nervous system selectively or diffusely are sedatives in the broader sense. Within the group of sedatives there exist substances which in large doses induce sleep with regularity. These drugs are hypnotics.

### TYPES OF SLEEP AND THE CHOICE OF HYPNOTICS

Hypnotics are symptomatic remedies, and they represent only one of the measures that are of aid in inducing sleep. Frequently, psychotherapeutic or physical measures directed at the core of the problem are to be preferred, and hypnotics serve but as adjuvants. An ideally correct selection of a soporific for a given patient will be possible only when both the mechanism of the disturbance of sleep and the manner of action of the drug to be used are known. Much will be accomplished through a better understanding of the interrelations between certain functions of the cortex, the diencephalon and the mesencephalon, on the one hand, and through the better localization of the seat of action of the sedatives and hypnotics, on the other hand.

All that is known today is that in the brain stem there exist areas the physical or chemical disturbance of which can result in an instantaneous sleeplike state.<sup>3</sup> The nervous centers responsible for regulation of con-

Sc.* 178: 390 (Sept.) 1929; (b) The Indications and Dangers of Sedatives and Hypnotics with Special Reference to the Barbituric Acid Derivatives, *Internat. Clin.* 1: 39 (March) 1936.

3. Hess, W. R.: The Autonomic Nervous System: Sleep as a Regulating Process, *Lancet* 2: 1259 (Dec. 10) 1932. Ferris, E. B., Jr.; Capps, R. B., and Weiss, Soma: Carotid Sinus Syncope and Its Bearing on the Mechanism of the Unconscious State and Convulsions, *Medicine* 14: 377 (Dec.) 1935.

sciousness and sleep are in some respects of parasympathetic character. Although recently acquired knowledge indicates that the different types of hypnotics reach diffusely all portions of the central nervous system,<sup>4</sup> there is nevertheless evidence that certain portions of the brain possess a selective chemical and functional susceptibility to the action of hypnotics. Thus, in spite of the fact that the barbiturates are taken up by all parts of the brain as well as by tissues of other organs, the disturbances of several vegetative functions in barbiturate hypnosis and the antagonistic effects of ephedrine, benzedrine and picrotoxin suggest a special reactivity of centers in the brain stem to this group of drugs. In this somewhat restricted sense there is justification for the division of hypnotics into two groups: one having predominantly a cortical action, such as bromides, paraldehyde, chloral hydrate, bromural and carbromal, and one having a relatively greater effect on the brain stem, such as the barbiturates.<sup>5</sup>

In the clinical selection of suitable hypnotics, an examination of the nature of the sleep habit of the patient is essential. It should be appreciated that sleep requirement varies considerably in normal persons. The refreshing effect of sleep is influenced by the degree of preceding physical and mental exertion, and particularly by emotional conflicts. In addition to the duration and the depth of the sleep, the character of the dream states is an important factor. The depth of sleep, as indicated by the intensity of stimulus required for awakening, is usually two or three times greater during the first two hours than thereafter, when slowly and progressively it becomes superficial.

In examining the more common types of disturbance of sleep, one finds that in persons who are nervously fatigued the difficulty often lies in the disturbance of the onset. Once sleep is established, the normal rhythm will continue. In such patients, mild or more potent hypnotics with short duration of action, such as bromural, carbromal or the sodium salt of *n*-methyl-cyclohexenyl-methyl barbituric acid (evipal), will be effective, with the advantage of no after-effects. In patients whose sleep remains superficial with frequent awakenings, milder hypnotics with relatively long duration of action, such as chloral, chloral hydrate, barbital, dial and phenobarbital, are indicated. In neurasthenic individuals the rapport between physician and patient is often symbolically transferred to the medication; hence even milk or water, with proper suggestion, often is effective. There is, however, a definite physiologic mechanism that is active here. The psychic factor also frequently plays a part in the effect of potent hypnotics. If the cause of disturbed sleep is pain, analgesics such as salicylates, acetophenetidin or codeine, administered alone or in combination with hypnotics, give good results, whereas hypnotics alone are ineffective. If motor restlessness is responsible for insomnia, as in infectious disease, hypnotics with dominant motor depressant effect, such as bromides and the barbiturates, are helpful. If a change is made from one type of hypnotic to another, it should be remembered that a synergism exists in their depressant effect on the vital centers. Hence, a full dose of any hypnotic can be given only after the dose administered previously is adequately eliminated.

These considerations indicate that hypnotics often do not act directly on the "sleep centers" but rather act

indirectly through elimination of the factors interfering with natural sleep. Such indirect induction of natural sleep is always to be preferred to the "forced" action of hypnotics on the nervous mechanism of sleep, as the latter type of sleep, notwithstanding its depth and duration, is not natural and often not refreshing.

#### CLASSIFICATION OF SEDATIVES AND HYPNOTICS

The sedatives and hypnotics are of heterogeneous chemical types. While among members of the same group a certain degree of relationship exists between the chemical structure and pharmacologic effects, no such relationship exists between the various types. Thus, some inorganic salts, just like some complex organic substances, are mild while others are powerful hypnotics; some have a short and others a long duration of action.

Much vogue and fashion exists in the use of sedatives and hypnotics. Today some of the older members of the group, such as acetophenetidin, acetanilid, aldehydes and carbamates, have fallen into undeserved disuse, whereas the more recently introduced drugs, such as the barbiturates, enjoy a popularity not always deserved. One may, with reservations, group the substances frequently used as sedatives and hypnotics, according to increasing therapeutic potency and toxicity, as follows: (1) the acetophenetidins, salicylates and anilids (primarily analgesics); inorganic salts, such as bromides, calcium (analgesic) and magnesium salts; (2) the alcohol and aldehyde groups, as represented mainly by ethyl alcohol, tribrom-ethanol, trichlorisopropyl alcohol, chlorbutanol (trichlortertiary butyl alcohol), on the one hand, and paraldehyde and chloral hydrate (trichloroacetaldehyde), on the other hand; (3) the sulfones, as represented by sulfonmethane and sulfonethylmethane; (4) the ureids, as represented by carbromal (bromdiethylacetylurea) and bromural ( $\alpha$ -monobromisovalerylurea); (5) the barbituric acid derivatives, as represented by a large number of substances, such as amylal, barbital, dial, ipral, neonal, nossal, pentobarbital, phanodorn, phenobarbital and sandoptal; (6) the hydrocarbons, such as acetylene, ethylene, cyclopropane, chloroform and ethyl chloride (used as anesthetics only), and (7) finally the morphine group, as represented by morphine, dilaudid and codeine. Some of these substances are primarily analgesic and do not possess a direct hypnotic effect, but they are often used as hypnotics because of their analgesic effects.

*Chemical Structure and Pharmacologic Action.*—There are a large number of hypnotics used in medicine, and the number of their theoretical possibilities is unlimited. Within the barbituric acid group alone, more than thirty preparations are available. These barbiturates, often recognized only through their trade names, are closely related both in chemical structure and in pharmacologic action. By altering the character of the side chains of their chemical structure, the main differences induced are (1) in the therapeutic and toxic doses, (2) in the induction and recovery times and, finally, (3) in the duration of sleep or persistence of action. The fact that the therapeutic dose of one substance is smaller than that of another does not indicate that the hypnotic is a better or a safer one. It is rather the ratio between the hypnotic and the toxic or fatal dose that is one of the important measures of pharmacologic fitness.

In spite of the fact that a certain type of chemical alteration tends to produce a certain type of change in the pharmacologic action, exceptions are not uncom-

4. Koppansy, Theodore; Dille, J. M., and Krop, Stephen: *Studies on Barbiturates*. VIII. Distribution of Barbiturates in the Brain, *J. Pharmacol. & Exper. Therap.* 52: 121 (Oct.) 1934.  
5. Pick, E. P.: *Die Grundlagen der Schlafmittel-Therapie*, *Fortschr. d. Therap.* 6: 161 (March 25) 1930.

mon. Hence, careful pharmacologic and therapeutic study of each member is essential. The following examples will serve to illustrate the changes in pharmacologic effects resulting from simple chemical alterations: While the methyl sulfones and methyl barbiturates are practically inert, the introduction of ethyl radicals creates a potent hypnotic effect. As far as the barbiturates are concerned, the longer the alkyl side chain, the greater in general are the hypnotic and toxic effects. Moreover, the saturation of the side chain has a significant effect on the behavior of the barbiturates in the body. The unsaturated members are inactivated by the liver and hence usually have a shorter duration of action, while the saturated barbiturates are eliminated more or less unaltered by the kidney and usually act over a longer period of time. Thus the intravenous administration of *n*-methyl-cyclohexenyl-methyl barbituric acid (evipal), containing a "heavy" side chain which readily disintegrates in the body, produces hypnosis measured in minutes, while a corresponding dose of diethylbarbituric acid (barbital) or phenylethyl barbituric acid (phenobarbital), substances which are not metabolized, can cause sleep of many hours' duration. Equally striking changes in biologic action can be induced by the introduction of or changes in halogen atoms. The difference in the effect of ethyl alcohol and of tribrom-ethanol is an outstanding example of such a change in chemical structure and pharmacologic effect.

#### ADMINISTRATION AND DOSAGE

Administration of hypnotics should be by mouth unless this is not feasible or is contraindicated. When oral administration is not possible, a soluble preparation may be given rectally by means of a starch enema. In patients with ulcerative lesions of the stomach or the duodenum, irritative hypnotics, such as chloral and chloral hydrate, should not be given by mouth. Some of the special indications for parenteral administration are delirium with threatening circulatory collapse especially if the patient resists oral or rectal administration, convulsive seizures from local anesthetics, grand mal seizures, tetanus with a tendency to marked spasms and convulsions, and severe cases of eclampsia. For parenteral use, paraldehyde and the barbituric acid derivatives are particularly suitable. As these drugs are irritant when given subcutaneously, they should be administered intramuscularly or intravenously. Intravenous injections should be given slowly, in the form of a relatively dilute solution.

Dosage is a relative amount of a drug essential for a desired therapeutic effect. Depending on the effect desired, some of the hypnotics are used in as widely varying a range as from 1 to 30. It holds true for all hypnotics that the more irritable the central nervous system, the greater is the dose required to induce sleep. Thus, in nervously fatigued persons, phenobarbital is used effectively in doses of 30 mg. (one-half grain) to enhance the natural tendency to sleep. In the presence of convulsions, on the other hand, doses of 1 Gm. (15 grains) or more are required to abolish the seizure and induce sleep. Any intense stimulus acting on the central nervous system can, within limits, counteract the effect of sedatives and hypnotics of all sorts. Contrariwise, if external and internal stimuli influencing the patient are reduced or eliminated, the effective dose will be smaller. It is for this reason that establishment of the general comfort of the patient through good nursing is always an effective adjuvant of drug sedation. The administration of large doses of

sedatives is justified only in serious emergencies, as previously indicated, and is attended with potential dangers.<sup>2</sup> One such inherent danger is the fluctuation in the state of irritability of the central nervous system. Thus, in order to overcome a convulsive seizure a relatively large dose of a hypnotic is essential. Following the cessation of the fit, however, the irritable state of the nervous system decreases, and frequently depression follows. In the latter state, then, the therapeutic dose administered under the former conditions becomes toxic.

In selecting the time of oral administration of hypnotics, the induction period is a determining factor. Certain hypnotics with a short induction period, such as chloral hydrate, paraldehyde, bromural, amyral and pentobarbital, can be taken effectively from one-half to one hour before retiring; others with a longer induction period, such as barbital, dial, ipral, phenobarbital and sulfonmethane, should be administered from one to two hours before the effect is desired.

The frequency of repetition of the dose depends on clinical indications and on the duration of action of the drug, and also on the patient's condition. Thus, in the presence of pain or muscular spasm, such as exists in tetanus, large doses of hypnotics with long duration of action may be efficacious for but three hours, while the same amount consumed by a normal person can produce deep sleep of several days' duration. Effort should always be made to discontinue the medication as soon as feasible. In case of prolonged use, it is preferable to change to other drugs of the same group or to another type of drug. It is also advisable not to prescribe hypnotics for more than two or three weeks without medical supervision. Such a procedure safeguards against the use of drugs for suicidal purposes.

#### UNTOWARD EFFECTS

Susceptibility to hypnotics depends partly on innate, partly on acquired, characteristics of the patient. Persons with sensitive and unstable nervous systems are particularly susceptible to the action of these drugs. Patients with anemia usually require smaller doses to achieve a given effect. As the detoxification and elimination of hypnotics are usually accomplished by the liver and kidneys, disease of these organs is frequently associated with increased susceptibility. Thus, the unsaturated barbituric acid derivatives, which are detoxified by the liver, can show intensified and prolonged action in the presence of diseases of the liver. I have observed two instances of poisoning with *n*-methyl-cyclohexenyl-methyl barbituric acid (evipal) of six and eight hours' duration in patients with liver disease following a dose which in a normal person would have a hypnotic effect for about twenty minutes. Other hypnotics that are not detoxified in the liver but are eliminated by the kidneys, such as bromides, barbital and phenobarbital, induce prolonged action in the presence of impaired renal function. It should also be borne in mind that regardless of through which organs hypnotics are metabolized or eliminated, inactivation is always dependent on an efficient circulation. Hence, in the presence of circulatory failure or collapse, effective elimination becomes seriously impaired and the hypnotic will remain active longer. Such prolonged action will then, in turn, add to the disintegration of the circulation, finally resulting in a vicious circle. This explains why drugs with a relatively short duration of action, such as tribrom-ethanol, can, in the presence of "shock," cause sleep of several days' duration. This is also one

of the main reasons why nonvolatile anesthetics are potentially dangerous agents in surgical practice.

When such pathologic states exist, particular precautions must accompany the use of hypnotics. Their careless use in peripheral circulatory failure, as judged from personal observations, is frequently responsible for fatalities, while the danger from direct action of hypnotics on the heart, often feared by physicians, is a negligible factor. In small therapeutic doses, hypnotics do not exert a detectable harmful effect on the heart.

**Habit Formation and Addiction.**—The evaluation of this problem is difficult, mainly because of the confusion that exists in the definition of terms. If one defines addiction as a bodily state which results in demonstrable disturbances of certain vegetative functions, such as occur after the withdrawal of morphine in habitués, then the commonly used hypnotics do not lead to addiction. On the other hand, it is common to find that, after prolonged administration of the members of the alcohol, aldehyde, urea or barbituric acid groups, patients crave their further use, and nervous disturbances may appear when they are discontinued. In this sense habit formation after the prolonged use of hypnotics is common. How far such habit formation is specific to the drug and how far it bears on the innate state of the patient it is difficult to judge. The prolonged use of these drugs is most common in individuals with emotional and mental difficulties, the very types of patients in whom not only formation of habits by suggestion but also development of conditioned reflexes occur with ease. Some of these subjects can acquire a habit to pink colored water if proper psychic influence is attached to its use. It is certain that in the majority of such instances the habit formation is psychologic. Nevertheless, in view of the fact that the difficulty experienced by the patient is practically identical regardless of whether the source of the habit is psychologic or chemical, every precaution should be taken to prevent the development of habit formation.

**Idiosyncrasy.**—Certain aspects of this problem bearing on susceptibility have already been discussed. Untoward reactions associated with confusion, lassitude, headache and accentuation of existing emotional states may occur after relatively large doses of any hypnotic, particularly in nervously hypersensitive persons. I have on several occasions observed that such drugs temporarily accentuated manic-depressive or paranoid tendencies in subjects with mild psychopathic personalities. In some of these patients the transient psychotic state seen after relatively large doses of hypnotics becomes established years later. Similarly, it is not rare in hospital practice to observe that confusion and psychotic tendencies become accentuated in patients with cardiac decompensation or infectious or certain deficiency diseases following attempted sedation with paraldehydes, chloral hydrate or the barbiturates.

Sometimes, then, under the effect of hypnotics, the underlying and heretofore partially controlled mental aberration becomes aggravated or brought to the surface from a subclinical stage. Such untoward effects precipitated by hypnotics are often not recognized, and the condition is aggravated by the further increase or repetition of the drug. It is difficult to state whether one type of hypnotic has a greater tendency to precipitate such conditions than others. Delirium precipitated by morphine may subside when barbiturates are administered, and toxic psychosis accentuated by a barbiturate may disappear after the administration of paralde-

hyde. One cannot generalize, however, but usually under such circumstances it is advisable to discontinue drug therapy and apply physical measures.

I have observed, as have Castin and Gardien,<sup>6</sup> patients with psychoneurotic personalities and insomnia in whom barbituric acid derivatives apparently precipitated ill defined, severe pain in the muscles or joints. The pain may be intense, particularly in the early hours of the morning, and may last for days or weeks after the drug has been discontinued. It is localized most frequently over the neck, shoulder and scapular regions and in the arms, and may appear in paroxysms.

In recent years dilaudid (dihydromorphinone hydrochloride) has been widely used as a morphine substitute. This drug is frequently utilized under the misconception that it is safer than morphine and that addiction does not develop. The pharmacologic and chemical evidence thus far available, however, suggests that the ratio between effective and toxic doses of morphine and of dilaudid, respectively, is essentially the same.<sup>7</sup> While tolerance to dilaudid develops with somewhat less ease than tolerance to morphine, nevertheless addiction to this drug has been reported. Although dilaudid may offer some advantage over morphine under special indications, the optimistic expectation and careless use that followed its earlier clinical trial are not justified.

Idiosyncrasy in the form of allergic or allergic-like reactions also may develop. This is apt to occur in patients with a tendency to asthma, angioneurotic edema, urticaria and severe menstrual difficulties. The presence of liver or renal abnormality can accentuate such tendencies. Among these reactions are the skin lesions precipitated by the bromides; toxic hepatitis following the administration of chloral, chloral hydrate or paraldehyde, and swelling of the eyelids, cheeks and lips, erythema and other exudative skin lesions, and, rarely, exfoliative dermatitis following the use of relatively small amounts of phenobarbital, allyl-isopropylbarbituric acid with aminopyrine and other barbituric acid derivatives. Pronounced reduction of blood platelets with hemorrhagic manifestations may develop from sensitivity to allyl-isopropylacetylurea (sedormid). I have observed two instances of such purpura. Purpura associated with increased capillary permeability and without hemorrhage from mucosae and reduction of platelets apparently may rarely result from chloral and paraldehyde. Agranulocytic angina has been precipitated by aminopyrine, but evidence is lacking so far to indicate that any one of the barbiturates alone is responsible for the precipitation of this condition.

#### CHRONIC INTOXICATION FROM PROLONGED MEDICATION

If doses of hypnotics are repeated before complete inactivation or complete elimination has taken place, nervous manifestations will appear as a result of the slow accumulation. Some of the features of chronic intoxication are the same regardless of the hypnotic administered; for example, a gradual loss of ambition, impairment of capacity for concentration and increasing desire to sleep. With certain types of hypnotics, particularly of the barbituric series, bizarre disturbances of the nervous system can develop which, if not recognized, can offer puzzling diagnostic problems. Chronic

6. Castin, P., and Gardien, P.: *Arthralgies et myalgies barbituriques*. Presse méd. 42: 1536 (Oct. 3) 1934.

7. Eddy, N. B.: Dilaudid (Dihydromorphinone Hydrochloride), J. A. M. A. 100: 1032 (April 1) 1933. Dilaudid (Dihydromorphinone): A Review of the Literature and a Study of Its Addictive Properties, U. S. Public Health Rep. supp. 113, U. S. Gov. Printing Office, Washington, 1935.

barbiturate poisoning, which nowadays is by far the most frequently observed chronic intoxication due to hypnotics, may manifest itself in vertigo, ataxia, nystagmus, visual hallucinations, difficulties with visual accommodation, thick speech, difficulty in the use of or paralysis of the limbs, or tremor. Suppression of the normal reflexes and appearance of changes in the pyramidal tract can complicate the clinical picture. The manifestations at times closely simulate the picture of epidemic encephalitis, pseudobulbar palsy, acute psychic depression, delirium tremens and cerebral vascular thrombosis. The heart is not affected, but there may be a tendency to pulmonary congestion. Rarely, albumin and casts appear in the urine. These manifestations disappear after discontinuance of the drug, though it may take two weeks or longer for complete recovery. This rather long period, out of proportion to the time required for chemical elimination of the drug, suggests that chronic intoxication consists not only in lack of elimination of the drug but also in a toxic effect on the structure of the nerve cells. Experimental evidence supports such a contention.<sup>8</sup> The appearance of chronic intoxication does not necessarily indicate the complete abandonment of medication; it rather makes desirable the better regulation of the dosage or the change to a preparation that has a shorter duration of action.

#### ACUTE POISONING

Acute poisoning seldom occurs as a result of individual susceptibility or following the administration of large therapeutic doses of hypnotics. It more frequently is due to ingestion of massive doses taken by mistake or with suicidal intent. In order to avoid accidental poisoning, it is advisable to instruct patients and their relatives not to keep bottles containing hypnotics at the bedside. During sleep, or during the accentuated confusion and reduced inhibition following the taking of a therapeutic dose, patients may unintentionally or subconsciously take toxic amounts. The use of hypnotics, particularly the barbiturates, is becoming the vogue in suicidal attempts. In view of the fact that the efficacy of the treatment of poisoning from barbiturates and other hypnotics is increasing, and since no permanent disability follows these intoxications, such a change in the trend toward suicide with hypnotics is welcomed, because the prognosis is better than with similar attempts with other chemicals, such as mercury, phosphorus and saponated solution of cresol.

The differences in the behavior of patients intoxicated with various types of hypnotics are inadequate for the clinical diagnosis of the nature of poisoning. This should be determined through circumstantial and preferably through chemical evidence. The clinical course of intoxication is always potentially treacherous. The primary danger in acute intoxication is the derangement of vital nerve centers and, as a consequence, circulatory collapse. In addition, several of the hypnotics are capillary poisons and change their permeability. Some, such as chloral hydrate and paraldehyde, possess a relatively greater depressant action on the vasomotor system than others, like the barbiturates, and circulatory collapse can develop unexpectedly and with great rapidity. The full development of the intoxication may take some time, because nausea closes the pylorus and thus retards absorption. In addition, as has already been indicated,

if there is a tendency to vasomotor collapse the inactivation of hypnotics becomes impaired and their action is prolonged and intensified. It is of practical significance that their depressant effect on the circulatory system is to some extent independent of their effect on the nervous system. Thus it is common experience to observe impairment of the peripheral circulation in pulmonary congestion and the development of a fatal bronchopneumonia days after the patient has regained consciousness. These late complications bear pertinently on the care of these patients.

The fatal dose of a hypnotic varies considerably depending on factors already discussed. We<sup>9</sup> have shown elsewhere the synergistic and antagonistic relationship that exists between the state of the respiratory center and the action of respiratory stimulants on the one hand and the action of depressants on the other. As far as the barbiturates are concerned, it has been stated that even small average hypnotic doses can cause dangerous or fatal reactions in organically normal subjects. Gillespie<sup>10</sup> has recently examined the literature and concluded that there is no case on record in which either a single dose or repeated doses of average therapeutic magnitude have caused death in the absence of complicating factors. This obviously does not refer to the rare instances of fatal skin reactions.

*Treatment.*—In instances of mild intoxication, withdrawal of the hypnotic alone relieves the symptoms. The principles of treatment of severe intoxications are (1) removal of the hypnotic from the gastro-intestinal canal, (2) counteraction of the depressant action on the central nervous system, (3) prevention and treatment of circulatory collapse and its secondary complications, and (4) specific measures.

Gastric lavage should be performed with rather warm solutions, even if the patient is attended several hours after the ingestion of the drug, because absorption from the stomach may become slow with the onset of coma. Furthermore, a warm solution in the stomach is an effective general stimulant and supplies body heat, which is often disturbed under such conditions. The head should be kept low during and after lavage in order to prevent aspiration pneumonia, a not infrequent cause of death in an otherwise responsive type of case. Before the removal of the stomach tube, from 30 to 60 cc. (1 to 2 ounces) of a 50 per cent magnesium sulfate solution should be left in the stomach. With disturbed heat regulation, proper covering and heaters should be placed along the extremities. As a preventive of hypostatic congestion of the lungs and pneumonia, the body should be turned from one side to the other at approximately hourly intervals. An adequate amount of fluid should be administered, and for caloric supply intravenous dextrose solution may be given. If pulmonary congestion or vasomotor collapse exists, from 50 to 100 cc. (2 to 3 ounces) of 50 per cent dextrose solution should be infused intravenously.

The underlying principle of the drug therapy of poisoning with hypnotics is the administration of substances that increase the excitability of the central nervous system, particularly of those centers on which the hypnotics in question act predominantly. Caffeine, pyridine-betacarboxylic acid, diethylamide (coramin) and

8. Pickworth, F. A.; Young, H. M. A., and Willcox, W. H.: Clinical and Pathological Effects of Hypnotic Drugs of Barbituric Acid and Sulphonal Groups, *Proc. Roy. Soc. Med. (Sect. Therap. & Pharm.)* 20: 13 (July) 1927.

strychnine are the drugs most frequently used. The effectiveness of these drugs has been demonstrated experimentally in such varying types of intoxication as those caused by morphine, chloral hydrate, tribromethanol and the barbiturates. Their dosage depends on the depth of the depression of the central nervous system. The improvement of the circulation following the administration of these substances is not due to direct action on the heart but rather to action on the vasomotor centers. Through the improved peripheral circulation, the detoxifying capacity of the body becomes increased; hence these drugs are more than symptomatic "awakening" remedies. The disadvantage of coramin is that the persistence of action is brief.<sup>11</sup> Haggard and Greenberg<sup>12</sup> have shown the efficacy of strychnine in experimental phenobarbital poisoning, and successful treatment of poisoning in man has been reported.<sup>13</sup> In severe types of poisoning I have administered strychnine at hourly intervals intravenously or subcutaneously, in doses up to 10 mg. (one-sixth grain). As improvement occurred the dosage was gradually decreased to 1 or 2 mg. ( $\frac{1}{60}$  to  $\frac{1}{30}$  grain). Ephedrine and related substances, such as benzedrine, can counteract sleep and stimulate centers in the brain stem. This action is beneficial in the treatment of experimental intoxication with hypnotics.<sup>14</sup> In severe barbituric poisoning I<sup>2b</sup> have administered from 15 to 30 mg. (one-fourth to one-half grain) of ephedrine intravenously or intramuscularly at two-hour intervals, alternating every hour with strychnine. Purves-Stewart and Willcox<sup>15</sup> have advocated in barbitol poisoning repeated drainage of the spinal fluid through lumbar puncture, taps, or preferably through cisternal drainage. According to these observers this procedure hastens the removal of the drug from the central nervous system and especially from the vital medullary centers, which are bathed by the poison in relatively high concentration. I have used this procedure as an adjuvant in the treatment of poisoning with saturated barbiturates such as barbital and phenobarbital, which are not inactivated within the body and hence are present in relatively high concentration in the spinal fluid.

#### CONCLUSION

These are, then, some of the general aspects of the clinical problem of the hypnotics. For the skilful use of these substances, additional specific knowledge bearing particularly on the pharmacologic characteristics of individual hypnotics and on the clinical evaluation of the patient is essential. The effective use of hypnotics demonstrates the necessity of knowledge of clinical as well as of biologic sciences in the daily work of the physician.

In clinical practice, the use of a few well selected and well studied hypnotics included in the United States Pharmacopeia or accepted by the Council on Pharmacy and Chemistry of the American Medical Association will yield better therapeutic results than the use of a large number of poorly understood hypnotics.

#### ABSTRACT OF DISCUSSION

DR. CHAUNCEY D. LEAKE, San Francisco: Is there any clinical advantage in utilizing the difference of action in drugs, such as the salicylates, which act by virtue of pulling fluid out of congested areas, and those, such as the morphine derivatives, which depress sensory pain perception? The first type would seem preferable in congestive pain, while the second would seem more useful in traumatic pain.

DR. SOMA WEISS, Boston: The difference in relieving pain with the aid of various types of analgesics is difficult to evaluate from clinical experience. All one can say is that in milder pain, especially the neuralgic type, salicylates or the acetophenetidin group may be very useful. In more severe pain my associates and I are using members of the morphine group. Whether any differentiation can be made in clinical medicine on the basis of pharmacologic action, I am not certain. In connection with this question I wish to emphasize once more that if the patient has pain and as a result suffers from sleeplessness, he may continue to be disturbed for weeks when hypnotics alone are administered, but when hypnotics such as the barbituric acid derivatives are combined with analgesics such as codeine one-half grain (0.03 Gm.) and, in addition, with an average dose of salicylates or acetophenetidin, remarkable improvement in sleep and the disappearance of the pain may result. Therefore, I believe that the intelligent and skilful combination of hypnotics and analgesics has a distinct place in medicine.

#### PRIORITY AMONG AMERICAN PHYSICIANS IN DEMONSTRATING THE CAUSE OF GRAIN ITCH

TARDY CREDIT THEREFOR GIVEN TO  
DR. LYMAN TALMAGE RAWLES

HERMAN E. KITREDGE, M.D.

Dermatologist to Saint Elizabeth's and Providence Hospitals; Associate Dermatologist to the Central Dispensary and Emergency Hospital; Clinical Instructor in Dermatology, George Washington University School of Medicine  
WASHINGTON, D. C.

Several years ago, in collecting medical and entomologic data for a professional paper, I<sup>1</sup> incidentally acquired the suspicion that, owing to certain unfortunate omissions and errors for which the original investigator himself was only partly responsible, credit for priority among American physicians in demonstrating the cause of grain itch had been given to the wrong men. Careful investigation, by way of literary research, correspondence and personal interview, transformed the suspicion into a firm conviction. I resolved that, when time permitted, I would review the relevant facts and give "credit where credit is due." Hence this paper.

#### HISTORY OF DERMATITIS FOLLOWING CONTACT WITH GRAIN OR STRAW, AND OF AN APPARENTLY ASSOCIATED MITE

It would lead quite beyond the scope and the scientific requirements of this paper to reproduce here in detail the vague and shadowy history of the dermatitis and of the apparently associated mite that, during the eighty years preceding 1909, intermittently engaged the troubled attention of laymen and the puzzled attention of physicians in Europe and America. That history has already been presented in sufficiently full outline by Webster,<sup>2</sup> Schamberg,<sup>3</sup> Rawles,<sup>4</sup> Stelwagon and

Gaskill<sup>5</sup> and others. It is therefore necessary to sketch here so much only of the history referred to as is requisite to a clear understanding of the subsequent sections of this paper.

*History in Europe.*—Dermatitis in laborers who had handled sacks of wheat or barley, or who had been in contact with the straw of those cereals, was observed by Lagreze-Fossat and Montane in France in 1849, by Robin in that country in 1867 and 1872, by Targioni-Tozzetti in Italy in 1875, by Geber in Hungary in 1879, by Koller in the same country in 1882 and by Flemming in Germany in 1884.<sup>6</sup>

Webster stated that the cases observed by Lagreze-Fossat and Montane and by Robin were due to *Pediculoides* [*Acarus*] *tritici* Lagreze-Fossat (1851) and that it "would seem quite probable" that the mite involved in the cases described by Geber was *Pediculoides ventricosus* Newport (1850). As to the cases observed by Koller and Flemming in Hungary and in Germany, respectively, Webster was less certain; but, since the Angoumois grain moth (*Sitotroga cerealella*), hereinafter shown to be a frequent host of *Pediculoides ventricosus*, is a very common pest in those countries, he suspected that the same mite was responsible.

Lastly, at the tenth meeting of the Italian Dermatologic Association, held in Rome in December 1908, Ducrey<sup>7</sup> and Sberna<sup>8</sup> presented papers showing that a certain epidemic of dermatitis was caused by *Pediculoides ventricosus* in wheat.

*History in America.*—American observations of dermatitis following contact with straw antedate the European. An itching eruption in persons who had slept in barley straw beds was noted in Massachusetts in 1829, 1831 and 1845, and in New York in 1879. There was no suspicion that a mite was responsible for the condition, the cause being assigned to certain grain parasites easily visible to the naked eye, such as *Meromyza americana* and *Isosoma hordei*, hereinafter mentioned as hosts of *Pediculoides ventricosus*. In much the same way as malarial fever was attributed to the "night air" itself, not to the plasmodium carried by mosquitoes in that air, so the dermatitis was attributed to the wholly innocent parasites of the wheat and the barley. And why not? For when the infesting *Meromyza* and *Isosoma* were burned with the straw, the dermatitis disappeared!

*First American Clinical Observation of the Mite.*—According to Webster,<sup>2</sup> the first American observation of *Pediculoides* itself in connection with the malady was made by Dr. Henry Skinner of Philadelphia about 1894 or 1896. The owner of a suburban boarding house, many inmates of which had been attacked by a "rashlike disease," supposed to have been contracted from their beds, submitted straw dust and debris from the mattresses of the suspected beds. On examination, Dr. Skinner found specimens of the mite. No further investigation was made.

*First Clinical Description of the Dermatitis.*—The next important event in the history of the condition occurred in 1901, when Schamberg<sup>9</sup> gave the first

clinical description, in a paper entitled "An Epidemic of a Peculiar and Unfamiliar Disease of the Skin." That contribution, although admirably crystallizing the previous vague and fragmentary accounts of the malady into a definite clinical entity recognizable by physicians, failed to assign a parasite or other agent to the etiologic rôle.

*History and Description of the Mite.*—In 1849 Mr. George Newport<sup>10</sup> of England discovered in the nest of a wasp (*Anthophora retusa*) at Gravesend a mite that he called *Heteropus ventricosus*, describing it in a paper read before the Linnean Society of London, March 5, 1850, and published, according to Kappel,<sup>11</sup> on October 18 of the same year. As the genus *Heteropus* was preoccupied, Targioni-Tozzetti,<sup>12</sup> in 1875, substituted the generic name *Pediculoides*; hence the present entomologically recognized nomenclature, *Pediculoides ventricosus* Newport (1850).

It is, according to Banks,<sup>13</sup> a true mite, of the class Arachnida, order Acarina, superfamily Sarcoptoidea, family Tarsonemidae, genus *Pediculoides*. Its synonyms, as listed by Carazza,<sup>14</sup> are *Heteropus ventricosus* Newport, 1850; *Acarus tritici* Lagreze-Fossat, 1851; *Physogaster larvarum* Lichtenstein, 1868; *Sphaerogyna ventricosa* Laboulbène e Megnin, 1885; *Pediculoides tritici* Targioni-Tozzetti, 1878.

It should be pointed out that, although Reuter<sup>15</sup> cited *Pediculoides ventricosus* Newport (1850) as a good species and made no mention of *Acarus tritici* Lagreze-Fossat (1851), and that although Carazza<sup>14</sup> named not only the latter but nearly all of the other alleged itch-producing grain mites as synonyms of *Pediculoides ventricosus* Newport (1850), there is still some doubt whether the latter is the only grain-infesting mite capable of causing grain itch. Thus Banks<sup>16</sup> in 1909, reporting on the *Pediculoides* that Schamberg and Goldberger had proved to be the cause of the disease in the cases studied by them, stated not that the incriminated mite was *Pediculoides ventricosus* Newport (1850) but that it was "very close to, if not identical with, the *Pediculoides ventricosus*."

With this and similar doubt-inspiring statements in mind, I recently appealed to Dr. H. E. Ewing of the Bureau of Entomology, than whom there is in the United States no higher authority on Acarina. Dr. Ewing responded as follows:

The only points in regard to the identity and proper scientific name of the American grain itch mite that I care to pass upon are the following:

1. All specimens of *Pediculoides* that I have examined, taken from man as suspected of attacking man, are *Pediculoides ventricosus* (Newport).

2. I have never been able to separate *Pediculoides* [*Acarus*] *tritici* Lagreze-Fossat from *Pediculoides ventricosus* (Newport). However, having never seen the types of either, I am in no position to say that they are the same.

I hope some European worker can straighten out the confusion existing between these species. It is a more fitting problem for one of them.

This frank and authoritative pronouncement leaves the matter in much the same status as before: The mite

described by Newport<sup>10</sup> causes grain itch; but whether it is the same mite that Lagreze-Fossat described a year later and, therefore, whether a mite that causes grain itch should be invariably called *Pediculoides ventricosus* Newport, are still uncertain. However, following the established American usage, the entomologic nomenclature employed in this paper as connoting the cause of grain itch will be *Pediculoides ventricosus* Newport.

This *Pediculoides* was recognized and entomologically identified, probably for the first time in America, by Webster<sup>2</sup> in 1882, while investigating, in southern Illinois, the ravages of the Angoumois grain moth, a frequent host of the mite. The latter, however, as indicated by Webster,<sup>2</sup> was doubtless abroad in the land "as early as 1830 [1829]," or twenty years before it was discovered in England.

*Pediculoides ventricosus* Newport is parasitic on the Angoumois grain moth (*Sitotroga cerealella*); on the wheat joint worm ([*Harmolita*] *Isosoma tritici* Fitch); on the wheat straw-worm (*Harmolita grandis* Riley); on the *Ditropinotus aureoviridis* Crawford (a hymenopterous insect known as a chalcid fly, and itself parasitic on the wheat jointworm, the wheat straw-worm and the like); on the larvae of *Bruchus*, infesting peas in Italy; on *Meromyza americana*, infesting the stems of wheat; on the barley jointworm (*Isosoma hordei*); on *Leptotrachelus dorsalis*, infesting wheat; on the periodic cicada (*Cicada septemdecim*); on the peach twig borer (*Anarsia lineatella*); on the cotton boll weevil (*Anthonomus grandis*) and the pepper weevil (*A. eugenii*); on wood-boring beetles, and on other soft-bodied insects and their larvae.

While this enumeration of the varied hosts of *Pediculoides* is of interest, as accounting for the far-flung incidence of the dermatitis of which it is now known to be the cause, it is with its activities as a parasite of the Angoumois grain moth, especially in the eastern part of the United States, and of the wheat jointworm in the midwestern states east of the Mississippi, that I shall be particularly concerned in the next section of this paper.

AMERICAN DEMONSTRATIONS THAT THE DERMATITIS FOLLOWING CONTACT WITH GRAIN OR STRAW IS CAUSED BY *PEDICULOIDES VENTRICOSUS*

*The Work of Schamberg and Goldberger.*—In the spring of 1909 an outbreak of the same "peculiar and unfamiliar disease of the skin" that was described by Schamberg<sup>9</sup> eight years before occurred among the crew of twenty sailors of a private yacht docked in the Delaware River at Philadelphia. Cases among the crews of other craft, and seventy cases in twenty separate households and boarding houses, brought the total number of victims to 123. The epidemic attracted the attention not only of the local health authorities of Philadelphia but of the federal government. The surgeon general of the United States Public Health and Marine Hospital Service ordered Passed Assistant Surgeon Joseph Goldberger of that service to Philadelphia to make an investigation of the malady, which he did in cooperation with Dr. Schamberg.

In nearly every case studied it was shown that the patient had been in contact with a new mattress made of wheat straw that had been received in small part from Indiana, but for the most part from southern New Jersey. The significance of these observations will become more clearly apparent in detailing the work of Rawles in Indiana and in pointing out the credit due

him. It is sufficient here to state that investigations by the United States Bureau of Entomology revealed the fact that, while nearly all the wheat straw on which Schamberg and Goldberger worked was infested with the Angoumois grain moth, only a small proportion harbored the wheat jointworm. Both of these parasites, however, are hosts of *Pediculoides ventricosus*—the grain moth being the predominant wheat pest in New Jersey; the jointworm, in Indiana.

It is unnecessary to review in detail Schamberg and Goldberger's investigations, the admirable thoroughness and scientific conclusiveness of which are not in question. They demonstrated the invariable presence of a mite in the straw from which the dermatitis was contracted, and they reproduced the dermatitis by exposing the human skin to the mite. The latter, as stated in the preceding section, was identified by Mr. Nathan Banks,<sup>16</sup> a noted expert on Acarina, Bureau of Entomology, not as *Pediculoides ventricosus* Newport but "as very close to, if not identical with, the *Pediculoides ventricosus*."

The investigators made no mention of having recovered *Pediculoides* from a lesion of the dermatitis.

Schamberg and Goldberger<sup>17</sup> began their work June 9, 1909, submitted a preliminary report of their observations June 21 and published that report July 9. A final or subsequent report, in no essential modifying the preliminary account, was published by Goldberger<sup>18</sup> June 10, 1910.

Since the preceding publications, such of the standard dermatologic textbooks as have treated of grain itch at all have either credited Schamberg and Goldberger as the sole discoverers of the cause of the disease or, if mentioning the work of Rawles, have given credit for priority of discovery to Schamberg and Goldberger. Only one treatise, that of Stelwagon and Gaskill,<sup>19</sup> as far as I have observed, has approached a just presentation of the facts. That volume stated: ". . . Goldberger and Schamberg, and, almost simultaneously, Rawles, were the first to associate convincingly cause and effect, and to identify the organism; Schamberg's investigations being extensive and conclusive." (The italics are mine.)

*The Work of Rawles.*—Approximately one month before Schamberg and Goldberger commenced their investigation of the epidemic of dermatitis in Philadelphia and its environs, another epidemic of the same disease began in the general section embracing northern Indiana. Sixty-one cases were studied by Dr. Lynan Talmage Rawles, an ambitious young man who had graduated four years previously from the Fort Wayne Medical College and who had settled in Hometown, a small country village ten miles north of Fort Wayne. That Dr. Rawles was imbued with the scientific spirit is evidenced by the fact that he was equipped with a microscope and accessories, rare implements in the armamentarium of the country doctor of over a quarter-century ago.

It will, I think, the more effectively subserve the interests of clarity, in endeavoring to point out the credit that is due to Rawles<sup>20</sup> as the original and independent American discoverer of the cause of grain itch,

17. Schamberg, J. F., and Goldberger, Joseph: Epidemic of an Urticarioid Dermatitis Due to a Small Mite (*Pediculoides Ventricosus*) in the Straw of Mattresses, Pub. Health Rep. 24, Nos. 27-53 (July-Dec.) 1909.

18. Goldberger, Joseph: The Straw Itch (Dermatitis Schambergi): A Disease New to American Physicians, Pub. Health Rep. 25: 779 (June 10) 1910.

20. Rawles, L. T.: Dermatitis *Ditropinotus Aureoviridis*; Synonym. Straw Itch, Indiana M. J. 2: 337 (Aug. 15) 1909.

if I first present his own account of his etiologic investigations, supplying later such omissions of dates, names and particulars as will give to that account the significance and importance that it deserves. He stated:

In May 1909 a very strikingly strange skin disease presented itself in this and surrounding country in epidemic form . . . limiting itself to the wheat growing sections.

The people generally affected were farmers and those living in small villages or towns where straw is used in beds, under carpets and around stables to bed stock. . . . The following incident led to an investigation as to the probable etiology:

A family had cleaned house, refilling the straw ticks of their beds and placed fresh straw under the carpets, and in about one week the family had developed this peculiar skin disease. In the beds was found a small, black fly, about the size of an ordinary gnat, which at first it appeared to be, but closer observation revealed that it was not of the gnat family. Upon examination of the straw it was found that a large number of the straws were perforated . . . through the bark of the straw, in the region of the joint, generally about two inches from the joint. The perforations were about the size of a small pinhole and ranging in number from ten to thirty in a straw. Upon section of the straw a small black fly was found under many of the openings through the bark.

Several flies were examined to ascertain if they possessed a piercing proboscis, and while observing one which had just been taken from under the bark of the straw, through which there was no perforation over the fly, a small mite was observed crawling over the dead body of the fly.

Placing the bodies of several flies under the microscope and using a  $\frac{1}{4}$ -inch objective and a No. 5 eyepiece, it was found that on nearly all flies over which the bark was intact a small parasite could be detected, these mites varying in number from two to four mites to each fly. Upon furthering the observations it was found that the dermatitis lasted after the flies had been observed and exterminated.

The following experiments were tried to prove whether it be the fly or the parasite that was the etiologic factor in producing the dermatitis:

Six live flies were taken, upon which no parasite could be found; these were placed under a watch glass and bound upon the right arm, leaving them in contact with the skin for three hours. Upon the left arm four dead flies, on which living parasites had been observed, were placed under a watch glass and left in contact with the skin for three hours, after which the glasses were removed and results awaited. The right arm showed nothing. Upon the left arm there appeared within twelve hours four small wheals, the character and evolution of which are later described.

To further experiments some fresh lesions of patients were scraped and the scrapings examined microscopically and two of the mites were found in the scrapings.

It is doubtful whether any other account of a medical investigation as succinct and straightforward as the preceding ever more completely failed to achieve what should have been its instant result; namely, to win credit for its author as the original and independent American discoverer of the cause of the disease concerned. Fortunately, however, the several specific names and dates which, inserted in the account, would have ensured its accomplishment of this are still available in Dr. Rawles's professional files.

Before presenting these data, so naively omitted by Rawles, it is necessary to introduce a few entomologic facts in order to make more intelligible the description of certain of Rawles's observations, such as the perforated straws, the mite-bearing "flies," and the like, and to the end that subsequent references to those features may be clearly understood.

There are several parasitic pests of wheat, but it is with only one of these, the wheat jointworm (*Harmolita*) *Isomoa tritici* Fitch, with which we are here concerned. This parasite, an insect, has four stages—egg, larva, pupa, adult. As an adult it is a black fly about

three-sixteenths inch long and looks somewhat as would an ant with wings. The egg is pushed down into the stem of the wheat plant with the ovipositor of the female, in May, passes through the stages of larva and pupa, and, the following May, having become an adult, gnaws a tiny circular hole, from within outward, through the side of the wheat stem, and, in a free environment, flies away in search of growing wheat, in which to initiate another life cycle.

These entomologic facts explain (1) the "perforations" in the straws, and (2) "the small black flies" in the straw-ticks of the beds, described by Rawles.<sup>20</sup> But they do not explain the far more important third factor noted by him—"the small mites crawling over the dead bodies of the flies," later reproducing the dermatitis, and still later recovered from the lesions of patients. This third factor is as readily accounted for as were the first and the second factors. Where straw is kept in a mass, as in a stack, a mow, a bale, or a bed-tick, *Pediculoides ventricosus* literally swarms through the mass, and when, in May, the adult jointworms begin to gnaw openings in the straw, the mites—many, many times smaller than the jointworms—enter through the beginning openings and kill all but about 5 per cent of the jointworms before the latter can enlarge the openings sufficiently to escape. This accounts for the third factor, the mites.

It now remains but to supplement Rawles's<sup>20</sup> original account with the specific names and dates previously mentioned to complete the detailed record of the original and independent American discovery of the cause of grain itch. Those names and dates<sup>21</sup> are embodied in the following paragraph:

In the spring of 1909, there lived at Huntertown a Mrs. Porter. Residing in the same house with her were her son and her son-in-law and his wife, Mr. and Mrs. Bert Darrow. During the week preceding April 26th, Mrs. Porter "cleaned house," refilling the bed-ticks with, and placing under the carpets, fresh wheat straw from a stack in her back lot. In so doing, Mrs. Porter contracted a "cold"; and, on April 26th, Dr. Rawles was summoned to her. On May 11th, Mr. Darrow came to Dr. Rawles's office with a skin eruption that the latter at first thought was urticaria. The patient stated that his wife, who had remained at home, was suffering with the same affection. Dr. Rawles prescribed for both. The next day Mr. Darrow, meeting Dr. Rawles on the street, told him that he (Darrow) and his wife were no better, and that his mother-in-law (Mrs. Porter) and his brother-in-law had the same disease. Two days later Mr. Darrow again came to Dr. Rawles's office, when scrapings, taken from lesions on the patient's back and microscopically examined by Dr. Rawles, showed the presence of mites. The patient remarked that since the new straw was put under the carpets at Mrs. Porter's the house had been "full of small flies," and he wondered whether the straw had anything to do with the flies and the "itch" with which all in the house were suffering. On the same day, Dr. Rawles and Mr. Darrow obtained from the stack in the back lot of Mrs. Porter's home specimens of the straw that had been put under the carpets, etc. With mite-bearing flies obtained from this straw, the etiologic investigations described in Dr. Rawles's<sup>20</sup> original paper were carried out.

Thus, on May 14, 1909, twenty-six days before Schamberg and Goldberger began their joint investiga-

21. Furnished in personal communications from Dr. Rawles.

tion, thirty-eight days before they submitted the preliminary report of their observations, and fifty-six days before they published that report, Rawles recovered mites from lesions of grain itch and reproduced those lesions by exposing the skin to the same mites.

Having confirmed, by repeated experiments on several other patients, during the week following May 14, the discoveries made on that date, Rawles's next step was to obtain an identification of the mite that he had proved to be the cause of the dermatitis. Accordingly, specimens of the straw with which he had been working, and which were known to contain the "flies" and the incriminated mite, were sent to the Department of Entomology, Purdue University, Lafayette, Ind., with explicit information as to the nature of the identification desired and as to the procedure which, in the light of the personal experience of Rawles in examining those particular specimens, was most likely to lead to success at the hands of the examining entomologist.

Here was an opportunity fraught with the highest importance, not only to Rawles but to many thousands of his fellow men. For eighty years the inhabitants of the grain-growing sections of America and Europe had been intermittently scratching; thousands of farm hands, of threshers, of handlers of grain, of the crews of water-craft, had been made miserable; boarding houses had been emptied of their inmates, and whole cargoes of cereals had been dumped into the water that those on board might be freed from a pestiferous dermatitis. The culprit mite at last had been captured, tried and found guilty; its sentence was only being postponed for want of a name. Dr. Rawles impatiently awaited the decision of the entomologic high court at Purdue. In a few days, the decision came and was as follows:<sup>20</sup>

The straws you sent are infested with the wheat-straw worm (*Isosoma tritici*), which gets inside of the main stem. The parasite which is working up on the fly is the *ditropinotus aureoviridis*. This is a new species of parasite, it having been described last year for the first time.

So the name of the convicted criminal was "*ditropinotus aureoviridis*"—surely too euphonic, even when misspelled in lower case, for a creature so vile!

As to the report as a whole, it is well to note, not in the spirit of pedantry but in that of science, that the straw was not "infested with the wheat-straw worm [i. e., the wheat straw-worm, *Harmolita grandis* Riley]" but with the wheat jointworm (*Harmolita*) *Isosoma tritici* Fitch, and that "the *ditropinotus aureoviridis* [*Ditropinotus aureoviridis* Crawford]"<sup>22</sup> was not "described last year [1908] for the first time" but in 1907.

In reading this report, scientifically inaccurate though it is, I realized that its incrimination of *Ditropinotus aureoviridis* as the cause of grain itch nevertheless pointed to the possibility that that dermatitis is not an etiologic entity but is due now to *Ditropinotus*, now to *Pediculoides*. Deciding to clear this point at first hand, I procured from the Bureau of Entomology living specimens of *Ditropinotus aureoviridis* Crawford, just as they were emerging in the adult, or fly stage, from the "cells" of the wheat jointworm, late in July 1933, and confined eleven of them on the flexor surface of my bare left forearm, under a small inverted Petri dish, for six hours. Not even the slightest irritation resulted. It was evident that *Ditropinotus aureoviridis* Crawford does not cause grain itch.

It did, however, cause several suspicions—among them the suspicion that the examining entomologist at Purdue did not see *Ditropinotus*. Rereading the letter from the chief of the Bureau of Entomology, dated July 18, stating that the specimens of *Ditropinotus* would be furnished, I noted the sentence "At the time this material is sent you, I shall also indicate the approximate date the adults may be expected to emerge from the jointworm cells." They did not emerge until ten days later, or July 28. Investigation revealed that this was evidently the second seasonal generation of the parasite, the first generation beginning to emerge, in this latitude, "about the first week in June." Even so, I wondered why *Ditropinotus* should refuse to emerge for a dermatologist in subtropical Washington before the first week in June but obligingly appear for a general practitioner and an entomologist in chilly northern Indiana at least two weeks earlier, or May 14, the date on which Rawles first saw the alleged *Ditropinotus* "crawling over the dead body of the fly." For, be it noted, if the entomologist at Purdue saw *Ditropinotus* on or about May 25, Rawles must have seen it May 14; for the two were looking at the same object, in the same situation—a parasite on a fly. Investigation of the seasonal habits of *Ditropinotus*, supplemented by correspondence with the Bureau of Entomology, Washington, and with the state agricultural experiment stations of Kentucky, Ohio, Illinois and Indiana, elicited the following facts: The eggs of *Ditropinotus aureoviridis* are deposited in the cells of the jointworm; the resulting larvae, full grown, pass the winter in the cells, beginning to emerge as adults (flies) "about the first week in June," in Virginia; between June 16 and June 27 in Kentucky; from "just prior to harvest" to "before fall" in Ohio, and from July 24 to August 30 in Illinois, and while there are "no [official state] records of the emergence of the *Ditropinotus aureoviridis*" in Indiana. Wildermuth, for the U. S. Bureau of Entomology, did find not only the latter insect but the wheat jointworm, both being parasitized by *Pediculoides ventricosus*, in straw in Rawles's barn, at Hometown, in December.

Thus it became clear, on the recorded testimony of competent entomologists, that even in Virginia, approximately 150 miles farther south than Hometown, Ind., the adult *Ditropinotus* does not emerge before the first week in June; that in Kentucky, in the same latitude as Virginia, it does not emerge until after the middle of June; that in Ohio and Illinois, in the same latitude as Indiana, it does not appear earlier than "just prior to harvest," and that in Indiana itself there is no official record of its emergence in spring, summer or fall. Therefore, it is highly improbable, if not impossible, that the "fly" in question was seen either at Hometown on May 14 or at Purdue about May 25.

Nor are the preceding facts the strongest available evidence that the examining entomologist did not see *Ditropinotus*. Just eight words of his report convict him "out of his own mouth." Those words are: "*The parasite which is working upon the fly.* . . ." (The italics are mine.) The "parasite" does not work "upon the fly." The adult *Ditropinotus* fly does not work upon the adult jointworm fly. The larva of *Ditropinotus* works upon the larva of the jointworm. "The larva," said Phillips and Poos,<sup>23</sup> "feeds almost continuously, if undisturbed, until nothing remains of the host larva but the empty skin." That is, when the *Ditropinotus* larva has finished with the jointworm larva there is

22. Crawford, J. C.: New North American Hymenoptera, J. New York Entomologic Soc. 15: 178, 1907.

23. Phillips, W. J., and Poos, F. W.: Life-History Studies of Three Joint Worm Parasites, J. Agric. Research 21: 412 (June 15) 1921.

nothing left—no adult jointworm fly develops. It is like the small boy eating the apple: "There ain't go'n' ta be no core!" Consequently, as far as *Ditropinotus* is concerned at all, the examining entomologist's report "The parasite which is working upon the fly is the *ditropenatus aureoviridis*" can be interpreted only as follows:

"The straws that you sent are infested with wheat jointworms that have never been attacked by *Ditropinotus aureoviridis*."

If, then, the parasite at work upon the fly was not *Ditropinotus aureoviridis*, what parasite was it? Since the straws sent to Purdue were from the same stack as those that Rawles had been studying; since the presence of both "flies" and mites in the straws was verified by Rawles just before the straws were sent; since the mites that Rawles saw "crawling over the dead bodies of the flies" were the same as those that he recovered from the lesions of Mr. Bert Darrow and other patients with grain itch, and the same as those with which he reproduced the disease, and since the only parasite known to be capable of causing grain itch is *Pediculoides ventricosus*, the parasite seen at Purdue about May 25, 1909, must have been *Pediculoides ventricosus*.

Indeed, this conclusion is confirmed in a personal communication recently received from Prof. J. J. Davis, the present chief in entomology at Purdue, who states that the parasite was "apparently . . . misidentified," and who quotes Webster<sup>24</sup> to the same effect, as follows:

Owing to an unfortunate misunderstanding, for which no one connected with these investigations [by the U. S. Bureau of Entomology] is responsible, Dr. Rawles did not receive a proper determination of the mite. . . . The entomological nomenclature in his paper . . . should therefore be corrected by substituting *Pediculoides ventricosus* for *Ditropinotus aureoviridis* wherever the latter name occurs. . . .

This gratifying announcement was no surprise to Rawles; for when Wildermuth, investigating for the bureau, visited Rawles at Hometown in December 1909 and showed him *Pediculoides ventricosus* in straw from his own barn, Rawles instantly recognized that mite as identical with the one which he had recovered from the lesions of Mr. Bert Darrow and other sufferers from grain itch, and with which he reproduced the disease on the preceding May 14.

And when Webster showed Schamberg<sup>3</sup> the mite found at Hometown by Wildermuth, Schamberg recognized it as identical with the one found by him and Goldberger at Philadelphia and identified by Banks<sup>16</sup> as "very close to, if not identical with, the *Pediculoides ventricosus*."

There is no certainty of the date on which *Pediculoides* was misidentified for Rawles, but careful investigation points to May 25. Equally uncertain is the date on which Rawles submitted the manuscript of the account of his discoveries to the *Journal of the Indiana State Medical Association*, in which it was published on Aug. 15, 1909. In the absence of any record, the editor's statement that the manuscript probably was received in June may be accepted as correct.

Nor does the date on which the manuscript was submitted, or the date on which the mite was misidentified, greatly matter. The significant facts remain that on May 14, 1909, twenty-six days before Schamberg and Goldberger began their joint investigation, Rawles recovered from lesions of grain itch a mite with which

he reproduced that disease and which was subsequently identified by Wildermuth and Webster<sup>2</sup> as *Pediculoides ventricosus*.

Rawles did his work—original and independent—in a small country village, without laboratory facilities, and, as is evident, far removed from those with entomologic knowledge and technical skill adequate to aid him, while Schamberg and Goldberger<sup>17</sup> worked in a great metropolitan medical center, with the well-nigh limitless resources of the United States Public Health and Marine Hospital Service and the United States Bureau of Entomology at their command.

#### RAWLES'S INCIDENTAL CONTRIBUTION TO ENTOMOLOGY

Nearly as notable as his discovery of the cause of grain itch was Rawles's incidental contribution to one of the problems of entomology.

I pointed out in an earlier section that the predominance of the Angoumois grain moth as a wheat pest in the Eastern states and as a host of *Pediculoides ventricosus* accounted for the origin, in the straw studied by Schamberg and Goldberger, of the epidemic of grain itch in the East. However, this threw no light on the origin of the widespread epidemic being investigated by Rawles, for the reason that the grain moth never occurs in great abundance in the Middle West except in grain kept in store in southern sections of Indiana and Illinois. Commenting on the effect of Rawles's discoveries in helping to solve this entomologic problem, Webster stated:<sup>24</sup>

Dr. Rawles's investigations were very carefully made and the results are exceedingly valuable for the reason that, in case of this western epidemic, he was able to trace the cause of the dermatitis to *Pediculoides ventricosus* and follow this back to the host insect, *Isosoma tritici*. This paper of Dr. Rawles . . . not only clears up the obscurity with reference to the cause of this epidemic in the Middle West . . . but, furthermore, these studies seem to solve the problem of the cause of the skin eruption noticed by Dr. Harris to have occurred as far back as 1830 [1829].

Thus Rawles, in proving that *Pediculoides ventricosus*, parasitic on the wheat jointworm, was the cause of the Midwestern epidemic of grain itch, demonstrated incidentally first, to entomologists, that the wheat jointworm was the predominant wheat pest of the corresponding region and secondly, to physicians, that the itching eruption noted eighty years before, in persons who had slept in beds of barley straw infested with the barley jointworm, probably was grain itch, caused by *Pediculoides ventricosus*, twenty years before that villainous mite was discovered.

#### CONCLUSIONS

1. The earliest observation of dermatitis following contact with straw or grain—probably what is now known as grain itch, caused by *Pediculoides ventricosus*—was made in Massachusetts, in 1829.<sup>25</sup>

2. The mite that is now entomologically known as *Pediculoides ventricosus* Newport<sup>10</sup> (1850) was discovered by Mr. George Newport of England in 1849 and was described by him as *Heteropus ventricosus* in 1850.

3. *Pediculoides ventricosus* was first entomologically identified in the United States by Webster<sup>2</sup> in 1882.

4. *Pediculoides ventricosus* apparently was first observed in the United States, in connection with what is now known as grain itch, by Dr. Henry Skinner<sup>26</sup> of Philadelphia, about 1894-1896.

25. Stelwagon, H. W., and Gaskill, H. K.,<sup>5</sup> p. 1243 (footnote).  
26. Skinner, Henry, cited by Webster.<sup>2</sup>

The first clinical description of what is now known as grain itch was published by Dr. Jay Frank Schamberg<sup>9</sup> July 6, 1901, under the title "An Epidemic of a Rare and Unfamiliar Disease of the Skin."

It is still uncertain whether *Pediculoides ventricosus* Newport<sup>10</sup> (1850) is the only grain-infesting insect capable of causing grain itch.

*Pediculoides ventricosus* was first recovered from a case of grain itch, at any rate in the United States, by Dr. Lyman Talmage Rawles, on May 14, 1909.

The first American demonstration that *Pediculoides ventricosus* is the cause of grain itch was made by Dr. Lyman Talmage Rawles on May 14, 1909.

The second American demonstration that *Pediculoides ventricosus* is the cause of grain itch was made by Drs. Jay Frank Schamberg and Joseph Goldberger<sup>17</sup> on June 9 and June 21, 1909.

Dr. Lyman Talmage Rawles was the original independent American discoverer of the cause of grain itch.

Columbia Medical Building.

## ACUTE COMPLETE GRANULOPENIA WITH DEATH DUE TO DINITROPHENOL POISONING

ALEXANDER GOLDMAN, M.D.

AND

MORDECAI HABER, M.D.

NEW YORK

There have been reports recently of ingestion of dinitrophenol (1-2-4) with subsequent psychic disturbances, vasomotor and circulatory changes, dermic reactions<sup>1</sup> and even an otologic complication.<sup>2</sup> Only three cases of agranulocytic angina following ingestion of dinitrophenol have been reported.<sup>3</sup> One case,<sup>4</sup> in which the drug was self administered in two weeks in doses of 100 mg. four times daily, the patient recovered following withdrawal of the drug, antigen therapy and the use of pentnucleotide. The second patient, taking 21,800 mg. in the form of "dinitrophen" over a period of four months, developed a picture of complete granulopenia with unfavorable reactions, such as sense of warmth, perspiration, headache, sore throat, vertigo and a pruritic eruption of the skin. These symptoms vanished in about three days following withdrawal of the drug but recurred with the repetition of the drug. This patient responded to pentnucleotide and blood transfusion.<sup>5</sup> In the third case,<sup>6</sup> 90 grains (5.8 Gm.) had been taken in a period of twenty days and subsequently nausea, diaphoresis, cyanosis and scleral icterus occurred, with ulceration of the pharynx, inflammation of the nasal and pharyngeal mucosa and of the gums and cervical adenopathy. This patient, under administration of leukocytic cream and pentnucleotide, began to show a response at the

end of the third day of treatment and was later discharged improved. Tainter and Wood<sup>7</sup> describe in detail a case reported by Geiger<sup>8</sup> in a short communication: A physician, informed of the effects of the drug, took a dose approximately seventeen times the recommended therapeutic or subfebrile dose of dinitrophenol. Restlessness, apprehension, progressive rise in temperature to 105.7 F., rapid pulse, profuse perspiration, delirium and, finally, coma and death characterized the eleven-hour course of the clinical picture. No blood count was reported nor was postmortem study of the bone marrow described.

In a series of eighteen cases of the ingestion of dinitrophenol reported by Masserman and Goldsmith,<sup>9</sup> who tried to evaluate the psychobiologic changes in schizophrenic patients by use of the drug, none of the blood pictures showed any change in cytology. This series includes one death from the administration of the drug but with no hematologic or bone marrow changes. In a series of 113 cases treated for obesity, no anginal symptoms followed the use of the drug. Blood studies were not reported.<sup>10</sup>

Because of the increasing number of deaths reported in the recent literature following the use of a drug the toxicity of which is still a matter of conjecture and because of the protean manifestations of this toxicity, we herewith submit the following report:

### REPORT OF CASE

**History.**—A Jewish girl, aged 13 years, was referred by Dr. J. M. Leavitt on July 1, 1934, at 7:30 p. m., with the following history: The patient had been taking dinitrophenol in 1½ grain (0.1 Gm.) capsules, one daily since May 15, at which time she weighed 265 pounds (120 Kg.). She had received 100 capsules from her family physician on May 15, with instructions to take one capsule daily. In a period of forty days the patient had lost 25 pounds (11 Kg.). By June 30, forty-six days later, only forty-six remaining capsules were found. At this time the patient began to complain of weakness, malaise, feverishness and sore throat and she began to vomit. On examination the patient, who had been in syncope, appeared asthenic and was delirious and occasionally euphoric. The head and face were warm. Respiration was irregular. The knee jerks were absent. Positive Murphy signs were present bilaterally. Submucous hemorrhages were seen on the soft palate, as were small areas of necrosis on the tip of the uvula and slight edema of the peritonsillar fossa. The tongue was dry, there was marked fetor oris and the cervical glands were enlarged and tender. Local treatment for the throat was applied, with no relief of symptoms.

The patient, admitted July 2 at 3:50 a. m., complained of vomiting, fever and sore throat of thirty-six hours' duration. The family history was essentially irrelevant. She had had measles, chickenpox, German measles and whooping cough in childhood. There had been no other previous illnesses or hospital admissions. The systems were normal except for the pronounced obesity since childhood. The menses had not yet begun. There was no history of allergic reactions. The present illness began on the morning of June 30, when the patient began to vomit apparently after a dietary indiscretion, the vomitus at first being partly digested food and later containing bile; the temperature was 101 F., which began to rise progressively to 105.6 F. The patient complained of pain in the throat and abdomen and of intense heat and thirst. At no time did the patient take aminopyrine or related drugs.

**Examination.**—On admission, the patient appeared acutely ill and was irrational. The face was flushed, circumoral pallor present and the skin hot and dry. The submaxillary glands

were palpable and tender, and the throat was deeply injected, with purulent exudate present on the tonsils and uvula. The pupils were contracted, were equal and regular, and gave a normal reaction to light (there was no accommodation, since the patient was irrational and uncooperative). The thyroid was not palpable. The heart was normal except for a tachycardia. The lungs were normal. The blood pressure was 100 systolic and 68 diastolic. The abdomen was normal except for a moderate number of silvery striae in the lateral aspects of the lower part of the abdomen. There was slight pretibial edema, knee jerks and tendon reflexes were diminished but equal, and no abnormal reflexes were present. The temperature was 105.6 F., the pulse was 136 and synchronous with the heart beat, and respirations were 32.

Laboratory examinations<sup>11</sup> revealed the following: Blood count: hemoglobin, 88 per cent; red blood cells, 4,600,000; white blood cells, 700; lymphocytes, 100 per cent; platelets, 180,000. Blood chemistry: dextrose, 148.2; urea 16.2; non-protein nitrogen, 35.3; uric acid, 3.2; creatinine, 1.23; cholesterol, 115.6; carbon dioxide combining power, 41.2 volumes per cent.

Examination of the urine showed the following: Specimen 1, July 1, was a dark amber and slightly cloudy. The Derrien test was positive for dinitrophenol.

Specimen 2, July 2, was a dark amber and slightly cloudy and had an acid reaction and a specific gravity of 1.019; albumin was 2 plus. It was negative for sugar, acetone, diacetic acid and urobilinogen; bile was present. There were very few fine and coarse granular casts, an occasional red blood cell and an occasional white blood cell. The Derrien test was negative for dinitrophenol.

Specimen 3, July 3, was orange, cloudy, acid, with a specific gravity of 1.017; albumin was 3 plus. It was negative for sugar, acetone and diacetic acid; bile was present. There were a few fine and coarsely granular casts, an occasional red blood cell and an occasional white blood cell. The Derrien test was negative for dinitrophenol.

Direct smear of the throat showed gram-positive cocci. Culture yielded *Streptococcus viridans* of the alpha type.

The diagnosis was dinitrophenol poisoning and secondary agranulocytic angina.

**Course of illness.**—Before admission, the patient had been given a high colonic irrigation, salicylates and sodium bicarbonate, 20 grains (1.3 Gm.) of each, instilled in a rectal drip and followed by hydrotherapy. The vomiting ceased and the tongue appeared less dry. On admission the patient was given a saline hypodermoclysis, 5 per cent dextrose intravenously, and a rectal drip totaling 3 liters of fluids. One-fourth grain (0.016 Gm.) of morphine was administered, repeated and supplemented with 2 cc. of 50 per cent magnesium sulfate. Two cubic centimeters of liver extract was given intramuscularly and repeated intravenously. The delirium, restlessness and perspiration persisted. A blood transfusion of 400 cc. of whole blood was given ten hours after admission, which improved the patient's condition somewhat. Twelve hours after admission the patient began to show signs of laryngeal edema; the temperature was 105.4 F.; the pulse was 120, of feeble tension, poor quality and irregular; respirations were 24 and stertorous in type; the lips and nails were cyanotic, the uvula and pharynx were markedly edematous, necrotic and cyanotic in color; the heart sounds were of fair quality, rapid and occasionally irregular. The patient was placed in an oxygen tent. An ice cold rectal drip was instituted and an ice pack was applied. The patient was still incoherent and restless, exhibiting a marked tremor of the body and incontinence of stools. Sedatives in the form of bromides and a mixture of opium and alkaloids were ineffective and frequent alcohol sponges were given; the temperature was still elevated to 105.4 F. The pulse was 130, intermittent and of poor quality. The patient was cyanotic and gasping for breath in spite of oxygen administered nasally. Twenty hours after admission the patient was taken to the operating room in a moribund condition; she was cyanotic and unconscious; breathing was barely audible with marked stridor, and the accessory muscles of respiration were in use. To combat the laryngeal stenosis, direct laryngoscopy

and bronchoscopy were attempted, but with failure, and tracheotomy was performed by Dr. Kleinfeld. At this point the patient's condition became much worse, and the bronchoscope was passed through the tracheotomy incision. The patient ceased breathing and failed to respond to artificial respiration, coramin and intracardiac epinephrine.

**Autopsy.**—The relevant postmortem observations were as follows:

External examination showed no ecchymosis or petechiae and moderate postmortem rigor, with no lividity present.

Subcutaneous fat was very pronounced. All abdominal organs appeared to be in normal position. The peritoneum was smooth and glistening.

The liver measured 27 by 16 cm. On section, the parenchyma showed advanced fatty changes.

The gallbladder was distended with about 20 cc. of greenish bile. No calculi were seen. The common, cystic and hepatic ducts were patent.

The pancreas measured 12 by 6 cm. No gross pathologic changes were noted.

The spleen measured 14 by 8 cm. The capsule was wrinkled. On section the pulp was friable and congested.

The stomach showed no gross pathologic changes.

In the small intestine there were numerous focal hemorrhagic necroses and some superficial ulceration in Peyer's patches and hyperplastic solitary acuminate lymph nodes.

No gross pathologic condition was noted in the large intestine.

Each kidney measured 19 by 9 cm. The capsules stripped easily. On section, no gross pathologic condition was noted.

Each adrenal measured 4 by 1 cm. and showed no gross pathologic changes.

No gross pathologic condition was present in the bladder.

The ureters were patent.

The uterus was small and infantile.

The ovaries showed numerous follicle cysts at the periphery.

The heart showed no free fluid in the pericardial cavity. The heart measured 9 by 7 cm. The musculature of the left ventricle measured 13 mm. in thickness. No gross pathologic condition was seen in the myocardium, endocardium or pericardium.

Each lung measured 20 by 10 cm. and showed no gross abnormal changes.

No adenopathy was present.

The thyroid measured 4 by 4 cm. No gross pathologic condition was noted.

There was no evidence of fracture of the skull. The meninges did not show abnormal changes. No pathologic changes were noted with regard to the cranial nerves. The ventricles showed no evidence of hemorrhage. The cut surfaces of the cortex, medulla, cerebellum, pons and proximal portion of the spinal cord showed no evidences of inflammation or of pathologic changes.

**Microscopic Examination.**—In the liver there were extensive fatty changes in the center of the liver lobule about the central vein.

The spleen showed extensive vascular congestion; there were hyaline thrombi present in the sinusoids.

The kidney presented evidence of acute hemorrhagic nephritis. Many lymphoblastic plasma cells were noted in the congested vessels, and tubular hemorrhages were present.

The lungs showed no noteworthy pathologic changes except for vascular congestion.

A colloid goiter was present in the thyroid with early focal calcific deposits.

The ovaries showed congestion of the ovarian vessels.

The pituitary showed vascular congestion.

There was no depression evident of the bone marrow activity in a study of the vertebral bone marrow.

There were several superficial ulcerations of the mucosa of the intestine.

Culture of the heart's blood proved negative.

A postmortem blood specimen gave a positive Derrien reaction for dinitrophenol.

#### COMMENT

Agranulocytic angina of Friedemann, agranulocytosis of Schultz, malignant neutropenia of Schilling, pernicious leukopenia of Fitz-Hugh and Krumbhaar and granulopenia are interchangeable terms, all designating

11. We are indebted to Dr. Joseph Felsen, director of laboratories and research, for the hematologic, chemical, bacteriologic and postmortem studies reported in this paper.

not only an absence of neutrophils but also a marked decrease in all the granulocytes. Our patient's blood smear showed only 700 white blood corpuscles, the cells being entirely lymphocytes. Of all the possible etiologic factors such as bacterial infection,<sup>12</sup> an allergic basis,<sup>13</sup> congenital weakness of the bone marrow,<sup>14</sup> an endocrine disturbance,<sup>15</sup> special bone marrow selectivity, aminopyrine and the benzene ring compounds, of which dinitrophenol is a member, the specific history of ingestion of the drug pointed definitely toward dinitrophenol. The drug was recovered from the urine and from the postmortem specimen of the heart's blood as exhibited by positive Derrien tests. Furthermore, the symptomatology and the clinical course of the case followed regularly, step by step, definite mechanistic characteristics of a granulopenic process.<sup>16</sup> Pathologic study of the bone marrow showed no depression of bone marrow activity. The significance of this is of debatable interpretation in view of nine necropsies in cases of granulopenia reported by Fitz-Hugh and Comroe.<sup>17</sup> Our patient took the drug in subfebrile doses for a period of forty days. She could have readily taken  $6\frac{1}{2}$  grains (420 mg.) daily with presumably no untoward effects,<sup>18</sup> since her weight was 265 pounds (120 Kg.). But her daily dosage was  $1\frac{1}{2}$  grains (97.5 mg.). Apparently the only possibility of explanation here is in the effect of cumulative toxicity of prolonged administration. Since there is no known antidote, treatment was aimed at supportive measures for the maintenance of the life and the strength of the patient and at bone marrow stimulation. Because of the rapid, fulminating course of the case, supportive measures were relied on mostly.

#### SUMMARY

1. There have been only four cases reported to date of acute granulopenia following ingestion of dinitrophenol. In three of these cases recovery occurred; the fourth ended fatally.
2. In our case death occurred eighty-four hours after the onset of symptoms of poisoning following the ingestion of dinitrophenol in subfebrile doses over a period of forty days. Agranulocytic anginal symptoms presented themselves thirty-six hours after onset.
3. Autopsy failed to reveal any changes in the granulopoietic system.
4. The patient weighed approximately 120 Kg. Her daily dosage, according to the work of Cutting and his associates,<sup>18</sup> could have been  $6\frac{1}{2}$  grains with no untoward effects over a prolonged period of time. However, this girl took only  $1\frac{1}{2}$  grains daily over a period of forty days, during which time she lost 25 pounds. On the forty-sixth day the patient showed a marked febrile reaction.
5. The dosage in this case was low over a prolonged period and certainly within the presumed limits of safety. Hence this fatality can be attributed either to cumulative toxicity or to an idiosyncrasy to the drug.
6. At present there is no criterion by which to evaluate the sensitivity of a patient to the drug.

17. Fitz-Hugh, Thomas, Jr., and Comroe, B. I.: *Am. J. M. Sc.* 185: 552 (April) 1933.  
18. Cutting, W. C.; Mehrtens, H. G., and Tainter, M. L.: *Actions and Uses of Dinitrophenol*, J. A. M. A. 101: 193 (July 15) 1933.

7. We have at our disposal, besides close supervision of the administration of the drug, the clinical measures of a check up of the daily temperatures and pulse rates, of blood counts, metabolic rates and weight loss.

8. There is no known specific antidote for dinitrophenol poisoning. The only remedy that seems to hold any promise, and which has been used efficaciously, is pentnucleotide. Unfortunately, because of the acute fulminating nature of the illness, it was not considered advisable to use pentnucleotide in our case. Other measures, such as oxygen, ice packs, alcohol sponges, iced proctoclyses, intravenous dextrose infusions and morphine, are essentially supportive in character.

Fulton Avenue at One Hundred and Sixty-Ninth Street.

#### EFFECTIVE METHOD OF TREATING AMEBIC ABSCESS OF THE LIVER

HAROLD L. JOSLYN, M.D.

ST. LOUIS

This paper is prompted by the fact that, in spite of definite and very marked lessening of the mortality rate in cases of amebic abscess of the liver treated by aspiration, the idea is little known in most parts of the country except those where amebiasis is common, the literature revealing that many of these patients are still subjected to surgery.

Rogers<sup>1</sup> in 1910 suggested the treatment of amebic abscesses by aspiration and reported several cases treated thus with good results. In 1920 Duckworth<sup>2</sup> mentioned treatment by aspiration and irrigation but did not report any cases. Ludlow<sup>3</sup> reported ten cases of amebic abscess treated by aspiration and emetine injections with no fatalities. Thurston<sup>4</sup> reported sixty-four cases treated with emetine and aspiration with a mortality rate of less than 25 per cent.

There are many advantages to treatment by this method over surgery. In the first place, by the time the diagnosis has been made the patients have suffered for some time with a chronic wasting disease and are poor surgical risks generally. In reported series of cases the surgical mortality has ranged well over 50 per cent. In the second place we are not dealing here with a true abscess; that is, there is no frank suppuration. The material obtained from the abscess consists only of necrotic liver tissue mixed with blood. In other words, if one can entirely evacuate the cavity and eradicate the cause there is little more we can hope to accomplish. Thirdly, these patients are usually ambulatory within a few days.

Contributing to the high surgical mortality is the fact that most of these cases with open drainage become secondarily infected, resulting in prolonged hospitalization, convalescence, and in many instances death.

#### DIAGNOSIS

A liver abscess should be suspected in every obscure case in which there is pain in the right upper quadrant of the abdomen with an enlarged and tender liver. Many of the abscesses rupture under the diaphragm, producing an elevation of the diaphragm with dulness,

From the St. Louis City Hospital.

absent breath sounds and voice sounds in the right lower part of the chest. X-ray examination reveals the elevated diaphragm. There is usually a history of fever, malaise, and perhaps chills for several weeks or months. A history of diarrhea or dysentery is helpful, but absence of such a history by no means rules out an abscess. Patients with such symptoms and signs in absence of other explanation deserve a cautious exploratory aspiration.

The majority of amebic abscesses are in the right lobe of the liver, and in nearly every instance they are large solitary lesions. The site of election for aspiration is in the tenth intercostal space either posteriorly or in the midaxillary line. The area is infiltrated with procaine hydrochloride and a 3 inch needle is inserted directly in until the typical reddish brown "pus" is obtained. As a rule the abscesses are large (from 300 to 400 cc. or larger) and very little difficulty is encountered in locating them. Frequently, by the time the patient presents himself to the doctor, the abscess has "pointed," and definite point tenderness may be elicited somewhere around the lower part of the thorax. In such a case the aspiration should be done in this region. In order to substantiate the diagnosis, after withdrawal of several hundred cubic centimeters of pus it is wise to instil 20 cc. of opaque oil and from 200 to 300 cc. of air into the abscess. It can then be outlined very nicely when the patient is roentgenographed in various positions.

#### METHOD OF TREATMENT

Once the diagnosis has been established, the patient is bridged across two beds in such a position that the part of the abscess nearest the surface will be in the most dependent position. In other words, if the abscess has "pointed" in the tenth intercostal space in the midaxillary line, the patient is placed on his right side with this region over the space between the beds. A large gage needle is then inserted into the tenth intercostal space and just through the wall of the abscess. The point of this needle is then in the most dependent portion of the abscess and in position to evacuate the contents of the lesion entirely. This needle is connected to a Wangenstein suction apparatus. A second large needle is then inserted into the abscess at any other point and connected to an ordinary gravity flask containing 1:2,500 emetine solution. The circuit is opened and the entire contents of the abscess are flushed out. In such a manner one evacuation is deemed sufficient. Several hundred cubic centimeters of the emetine solution is left within the cavity.

Simultaneously, the patient is started on emetine hydrochloride according to the method suggested by Reed,<sup>5</sup> 1 grain (0.065 Gm.) of emetine hypodermically for six days followed by one-half grain (0.03 Gm.) for eight days, making a total course of 10 grains (0.65 Gm.). As brought out by Reed, emetine in larger doses may be quite toxic and this course of ten grains has proved to be sufficient. The response to such treatment is rapid. Within a few days the patient feels normal, is free from fever and is allowed up. The liver shrinks markedly and approaches normal size. The patient is allowed to go home and told to return every month for a check up and x-ray examination of the liver. Though the patient is symptom free, it requires several months for the abscess to disappear. Instead of giving the emetine hypodermically, Soper<sup>6</sup> has obtained

excellent results by the use of emetine hydrochloride intravenously, giving 1 grain a day for seven days.

When the hepatic amebiasis has subsided, the patient should be given a thorough course of carbarsone to eliminate any remaining intestinal amebiasis. Arsenicals such as carbarsone and acetarsone are naturally contraindicated in hepatic amebiasis.

#### REPORT OF CASES

CASE 1.—E. J., a white man, aged 35, entered the hospital Nov. 25, 1935, complaining of gradual loss of weight and strength, malaise and fever, growing progressively worse for three months. He also complained of pain in the right shoulder for three weeks. He had several night sweats. On close questioning he stated that for five or six months he had had from four to five soft brown stools a day, without blood. His physician told him it was normal for some people to have this many stools. The history was essentially negative otherwise.

The patient was emaciated, with dulness, absent breath sounds and voice sounds in the right lower part of the chest. The blood pressure was 108 systolic, 60 diastolic. The liver was down four fingerbreadths below the costal margin and was moderately tender. The heart was regular without murmurs. The apex beat was in the fifth intercostal space in the nipple line. The temperature was 103, pulse 114, respiration 26. The urine was normal. Blood culture gave negative results. The Kahn reaction was negative. The blood sugar was 112 mg. per hundred cubic centimeters of blood; nonprotein nitrogen, 23 mg. Red blood cells numbered 4,904,000, white blood cells 20,400, with basophils, eosinophils and myelocytes 0 per cent, juveniles 4 per cent, stabkernige 33 per cent, segmented forms 44 per cent, lymphocytes 19 per cent, monocytes 0 per cent and hemoglobin 85 per cent.

Proctoscopic examination revealed from ten to fifteen shallow ulcers the size of match heads in the lower sigmoid. Some of the material from these ulcers was placed on a slide with warm saline solution and proved to be swarming with motile amebas containing red blood cells. X-ray examination of the chest revealed a density in the right base which was suggestive of an elevated diaphragm. A needle was inserted into the tenth intercostal space posteriorly and 750 cc. of dark brown "pus" aspirated. Twenty cc. of opaque oil was then instilled into the abscess and x-ray examination revealed this to be in the middle of the liver. The patient was treated by the method described. He became free from fever within a few days and has made an uneventful recovery, gaining 20 pounds (9 Kg.) within two months. The diminution in size of the abscess was followed by x-ray examination.

CASE 2.—J. H., a white man, aged 35, entered the hospital Jan. 21, 1936, complaining of a sharp pain in the right upper quadrant of two weeks' duration. He also stated that he had had an intermittent diarrhea of one month's duration, for which he had taken some medicine obtained from the drug store. The stools were watery with tenesmus, but there was no blood. On admission there was no diarrhea.

The patient was well nourished and appeared acutely ill. No definite abnormalities were apparent in the lung fields. The heart was regular, with no murmurs, and was not enlarged. The liver was four fingerbreadths below the costal margin and quite tender. In the tenth and eleventh intercostal spaces in the midaxillary line there was moderate fullness and definite point tenderness in the tenth intercostal space in the midaxillary line. The temperature was 100, pulse 88, respiration 32. The Kahn reaction was negative. Nonprotein nitrogen was 25 mg. per hundred cubic centimeters of blood, blood sugar 72 mg., amylase 12. Red blood cells numbered 3,000,000, white blood cells 16,900, basophils, eosinophils, myelocytes and juveniles, 0 per cent, stabkernige 18 per cent, lymphocytes 18 per cent, segmented forms 64 per cent, monocytes, 0 per cent, hemoglobin 75 per cent.

Proctoscopic examination revealed a normal mucosa in the sigmoid and rectum with no evidence of ulceration or bleeding.

In view of the observations, a needle was inserted into the tenth intercostal space at the region of point tenderness and the typical chocolate colored material of an amebic abscess obtained. Eight hundred cc. of the "pus" was aspirated and 500 cc. of air instilled along with 20 cc. of opaque oil to facil-

itate x-ray studies. The stools were consistently negative for blood or amebas.

Two days later drainage and irrigation were performed in the manner described. Two days following this the temperature, pulse and respiration were normal and have remained so. The patient was out of bed in five days and made a rapid recovery, gaining 35 pounds (16 Kg.) in eight weeks.

3701 Westminister Place.

## THE SUCCESSFUL TREATMENT OF ESSENTIAL THROMBOPENIA WITH HEMORRHAGE BY ROENTGEN RAYS

HILLYER RUDISILL JR., M.D.

CHARLESTON, S. C.

Stephan,<sup>1</sup> only four years after Frank's<sup>2</sup> description and separation of thrombopenic purpura as a distinct entity, resorted to roentgen treatments over the spleen and reported cures of two "fulminating" cases with this method. From this time there have been numerous reports of single cases or small series by irradiation. While some of the reported results have been favorable,<sup>3</sup> there have been some reports, as of Pancoast and his co-workers,<sup>4</sup> that have failed to confirm Stephan's enthusiastic and completely satisfactory pioneer efforts. Because of this, irradiation of the spleen is not universally accepted as being worth while and in the last few years seems to have fallen into disuse. This is strikingly shown in the series of Jones and Tocantins.<sup>5</sup> In their series of fifty-three patients only one was treated with x-rays. Fowler<sup>6</sup> in a recent review of 160 cases casually mentions x-rays as follows: "The use of roentgen rays over the spleen has been found to be of only temporary value."

tically a specific therapeutic agent in primary or uncomplicated thrombopenia with hemorrhage.

The present generally accepted worth of roentgen treatment cannot be better summarized than in the following quotations. These excerpts are from three of the best and most widely used textbooks on general medicine and treatment:

Irradiation of the spleen with roentgen rays has been advised in purpura haemorrhagica. It may be beneficial when appropriately given but rather often will be found ineffective.<sup>7</sup>

Irradiation of the spleen with small doses of x-rays occasionally benefits a patient somewhat.<sup>8</sup>

In the third textbook,<sup>9</sup> roentgen treatment is completely ignored.

### RESULTS IN THE PRESENT SERIES

My associates and I have successfully treated seven cases of purpuric and nonpurpuric thrombopenia with hemorrhage by irradiation of the spleen with x-rays. The eighth case, which was complicated with acute myeloid leukemia, terminated unfavorably.

### COMMENT ON CASES

Patient 2 had a 500 cc. transfusion of whole blood with no effect before x-rays were resorted to.

Patient 3 had 20 cc. of antivenin with no effect, prior to irradiation, but five days later after the thrombopenia had disappeared and the bleeding had ceased the patient developed an anaphylactoid purpura (Henoch-Schönlein type) from the antivenin. This was easily controlled with epinephrine and ephedrine.

Case 5 has been reported in detail by de Saussure and Townsend.<sup>10</sup>

Patient 6 has had great improvement in general health following the use of thyro-ovarian medication.

Case 7 has not been included in the table. The patient was a white boy, aged 8 years, who continued to bleed from an incision for the removal of infected inguinal glands. A diag-

Summary of Eight Cases in Which Roentgen Treatment Resulted in Complete Arrest of Thrombopenia

Case	Race	Sex	Age	Diagnosis	Manifestations	Platelet Count		Follow Up	No. of X-Ray Treatments
						Admission	Dismissal		
1. E. Q.	White	♀	29	Purpuric thrombopenia	Bleeding from gastro-intestinal and genito-urinary tracts; purpurae	11/3/32 20,000	11/18/32 210,000	5/1/36 No return	6

nosis of thrombopenia with hemorrhage with a platelet count of 25,000 was made. An additional diagnosis of acute myeloid leukemia was made forty-eight hours later. Following three roentgen treatments to the spleen the platelet count went up to 85,000 but the leukemia could not be controlled and the child died Dec. 13, 1934, six weeks after admission.

I believe, in spite of the smallness of the series, that uncomplicated thrombopenia with hemorrhage should be divided into two distinctly different classes; cases of unknown etiology (probably endocrine in origin), as cases 1, 6 and 8, and others from various toxemias,

cases 2, 3, 4 and 5.<sup>11</sup> For convenience I have termed these respectively as cases with an excessive S factor (overdestruction of platelets by the spleen) and the others of C factor type (toxic destruction of platelets in the circulation). This division is important from the standpoint of radiation treatment. In the C factor type the spleen's normal function needs only to be lowered until the toxemia is overcome, and from one to three roentgen treatments will usually accomplish this. In the S factor type, unless the patient responds partially to other forms of therapy also it may be occasionally necessary to render the spleen permanently functionless by intensive irradiation.

#### TECHNIC OF THE TREATMENTS

The same technical factors were purposely used throughout this series. The generator is a one-half wave, valve rectified, 220 kilovolt peak capacity installation. The tube has been a thick glass, large bulb, open bowl, high voltage therapy apparatus of the Coolidge type. The following were used in all of the treatments: voltage, 200 kilovolt peak; tube current, 4 milliamperes; filter, 0.5 mm. of copper plus 1 mm. of aluminum; roentgens per treatment, 200 measured in air; roentgens per minute, 10; area exposed, anteriorly over the spleen; size of field, 20 cm. circular.

#### CONCLUSION

Roentgen radiation constitutes an exceedingly valuable and possibly a specific therapeutic agent when applied over the spleen in primary or uncomplicated thrombopenia with hemorrhage either with or without purpuric skin manifestations.

#### THROMBOCYTOPENIC PURPURA INDUCED BY PERTUSSIS TOXIN IN ALLERGIC CHILDREN

I. NEWTON KUGELMASS, M.D., NEW YORK

Immunization against whooping cough is not without its dangers. They depend more on the constitution of the child than on the toxicity of the vaccine. Three allergic children developed thrombocytopenic purpura following the subcutaneous injections of B. pertussis vaccine obtained from different sources. The onset of the purpura came as a surprise without any premonitory signs by which the condition could be foretold. In one case purpura appeared within ten days, in the second during the second week and in the third case during the third week after the final injections. The purpura can be attributed to the activation of a preexisting but latent hemorrhagic state in one child. But in the two other children it is necessary to look for the pathologic lesion engendered by the pertussis toxin. And from the rarity of thrombocytopenic purpura as a complication in immunization it is apparently dependent on the allergic constitution.

The genesis of the purpuric state involves capillary toxicosis, megakaryocyte injury or both. There is ample clinical and experimental evidence that pertussis toxin is capable of inflicting such damage. B. pertussis forms no exotoxin, but an endotoxin is obtained from cultures which produces, experimentally, hemorrhagic lesions in animals. The contention that hemorrhagic manifestations observed in whooping cough are mechanical in origin is not substantiated by careful study. In an epidemic of whooping cough in an infantorium I observed

hemorrhages in the conjunctiva, gums and lips, petechiae in the skin and blood in the urine and stool. The infants had ample antiscorbutic protection and no latent hemorrhagic disease prevailed. In fact, more hemorrhagic symptoms were observed when the coughing was least severe. In all specific fevers some form of purpura may be the complication. But following immunization against pertussis only localized subcutaneous hemorrhages appeared at the site of injection in many children and purpura was induced in the following three cases:

CASE 1.—S. S., an allergic girl aged 4 years, referred by Dr. Tully of New Castle, Ind., developed purpura within ten days of immunization against whooping cough in September 1935. Large ecchymoses suddenly appeared throughout the body assuming the characteristics of hemorrhagic hives. Oozing from the gums and petechiae of the mucous membranes occurred following ingestion of solid food. There was no epistaxis or blood in the urine or stool. The condition persisted for six weeks, with a slight elevation of temperature. No drugs were offered the child during the immunization, nor was the purpura preceded by any infection. Spontaneous recurrences of milder nature appeared in November and again in December 1935.

Physical examination during the last episode showed fine petechiae throughout, sparsely distributed. The mucous membranes were unaffected. The eyes were puffy, the nasal breathing obstructed, and there was a postnasal drip, cervical lymphadenitis, retro-auricular intertrigo and a positive tourniquet test. The spleen was not palpable, the liver not enlarged. The child was found sensitive to the toxin of pertussis and to that of the organisms obtained from the maxillary sinuses. The blood showed 81 per cent hemoglobin, 4,600,000 red blood cells, 11,200 white blood cells, 47 per cent polymorphonuclears, 29 per cent lymphocytes, 12 per cent staff cells, of which 8 per cent were eosinophils, and 129,000 platelets, a rise from 88,000. The clotting time was five minutes, the bleeding time five minutes. The blood group was II. Transfusion was performed, the patient was maintained on a nonallergic diet, and the sinuses were treated. The child has remained free from purpura to date.

CASE 2.—T. M., an allergic child aged 2 years, referred by Dr. Lathrop of Plainfield, N. J., developed an exacerbation of purpura within the third week of immunization against whooping cough in July 1935. Confluent purpuric spots appeared over the lower extremities, with no other hemorrhagic manifestations. The blood showed a mild secondary anemia, platelets 85,000, bleeding time seventeen minutes, clotting time five minutes, clot retraction delayed. The tourniquet test was positive. There was no evidence of infectious invasion. The spleen was palpable at the costal border. The condition promptly abated with a transfusion, intramuscular blood and a clotting dietary.

The child had recovered from the first attack of purpura ten months previous to the immunization against whooping cough. At 5 months of age the gums over the erupting first incisors appeared hemorrhagic. Transient purpuric eruptions developed over increasing areas of the lower extremities. The physical examinations gave negative results. The blood picture was characteristic, with 34,000 platelets; the bleeding time was thirty minutes, clot retraction was markedly delayed, and the tourniquet test was positive. With a nonallergic clotting regimen and a transfusion the child recovered, the platelets having risen to 600,000.

CASE 3.—A. C., an allergic girl aged 5 years, referred by Dr. Sarkany of Long Island, developed purpura during the second week of the final immunizing dose of whooping cough vaccine in April 1936. Large ecchymoses appeared over the face and left arm and later similar patches, firm, raised and plum colored, covered the eyes, wrists and backs of the hands. There was occasional but slight epistaxis and hematuria and some elevation of temperature but no disturbance in the child's demeanor. The bleeding time, clotting time, blood count and platelet content were essentially normal. The condition gradually abated, when within a fortnight a paroxysmal cough developed which aggravated the purpura.

Physical examination showed waxy pallor and subconjunctival and cutaneous hemorrhages. A symmetrical dark purpuric

11. The toxic factors were, in order, case 2, acute specific urethritis and rheumatic fever; case 3 followed German measles; case 4 was associated with pyogenic cervical adenitis, and in case 5 there was a toxemia of pregnancy.

area covered the cheeks and nose. There were small petechiae over the trunk and limbs but none involving the mucous membranes. The ecchymoses were adjacent to bony prominences and pressure points with slight trauma apparently localizing the bleeding. The temperature was high, the pulse was rapid, the respirations were shallow. The pharynx was injected and the cervical lymph glands were enlarged. There were coarse mucous râles throughout the chest. The spleen was not palpable and the liver not enlarged. The reflexes were normal. Early one morning the child became restless, screamed and was found semiconscious. The head was retracted, breathing was stertorous, the movements of the extremities were involuntary. There was also involuntary micturition and defecation. There were all the evidences of a complete right-sided hemiplegia, an upper motor neuron lesion spreading to the left side and finally involving the whole body. With embarrassment of the vital centers she died five hours after the onset of the cerebral hemorrhage that morning.

1060 Park Avenue.

#### THE USE OF CARBON TETRACHLORIDE IN THE REMOVAL OF ADHESIVE TAPE

REPORT OF A NEAR FATAL CASE

FREMONT A. CHANDLER, M.D., CHICAGO

In view of the aroused interest in adhesive solvents since the recent tragic accident in a midwestern university training camp in which two lives were lost, there is danger of exchanging fire hazards for less familiar, asphyxiative ones. Benzine or similar products are inflammable and must be protected from open flames or sparks. These products are more efficient in the removal of adhesive tape and of desquamated epithelium. They are well tolerated by young patients. The potential danger of fire is probably only slightly greater than that present in the use of alcohol solutions which are on every dressing tray or cart.

On the other hand, carbon tetrachloride softens desquamating skin only slightly. Its odor is offensive to children who have had recent anesthetics.

Carbon tetrachloride and similar chemicals have definite and dangerous anesthetic properties. A recent issue of *Time* describes the use of carbon tetrachloride as a means of killing foxes so as not to injure their pelts. The vapor is heavy, a feature enhancing its use as a fire extinguisher. Its use by some otolaryngologists in irrigating the external auditory meatus is to be condemned because of the possibility of leakage into the pharynx by way of the eustachian tube.<sup>1</sup>

The following case is reported to show that the free circulation of air in a large, open ward is not sufficient to eliminate the anesthetic properties of carbon tetrachloride under certain conditions:

C. P., a white girl, aged 4 years, had tuberculous spondylitis of the third and fourth and the seventh and eighth dorsal

vertebrae of eighteen months' duration. A spine fusion operation to immobilize the diseased area of the spine was performed without any shocking effect on the patient. Convalescence was highly satisfactory. Solid food was tolerated within twelve hours. The operative dressings, which were held in place by adhesive tape, were changed on the fourth day by the intern. While he was removing the dressings, the child was prone. Carbon tetrachloride, which had been substituted for benzine by the hospital authorities because of the potential fire hazard, was used as a solvent to facilitate the removal of the dressings (see illustration). The patient collapsed suddenly, respirations ceased and the radial pulse became impalpable. Death appeared imminent. Artificial respiration was instituted. In about five

Method of removing adhesive tape from the back, showing spread of heavy asphyxiating vapor of carbon tetrachloride.

minutes the pulse returned, as did active respiration, at first feebly, and then stronger. In about ten minutes the child was quite normal. The subsequent convalescence has been uneventful.

This case is reported as a warning against the indiscriminate use of carbon tetrachloride in the removal of dressings from the upper part of the body, head and neck.

The presentation of carbon tetrachloride solutions and allied substances as safe solvents for the removal of adhesive tape under certain circumstances must be questioned. The layman is probably more familiar with the dangers of inflammatory mixtures than with those of heavy vapors possessing toxic potentialities.

6 North Michigan Avenue.

#### AMEBIASIS AND PSEUDOPOLYPOSIS OF THE COLON

HAMILTON H. ANDERSON, M.D.; DANIEL DELPRAT, M.D.;  
ALANSON WEEKS, M.D., AND ALFRED C. REED, M.D.  
SAN FRANCISCO

Although polyposis of the colon is not uncommon and malignant transformation is known to occur,<sup>1</sup> the etiology of polyps is still a matter of conjecture. In fact, we seem no closer to the solution of this problem than Wagner<sup>2</sup> was in 1832 when he "described the formation during the healing process of pedunculated polypoid, little warts on the margins of the ulcers and on certain smooth patches on their surface." He evidently did not suspect, however, that the warts were really folds of the diseased mucous membrane itself.<sup>3</sup> Irregular, polypoid masses of mucosa are often found at the margins of ulcers in the process of healing or are formed by the undermining of part of the mucosa in cases of chronic dysentery and chronic ulcerative colitis. Woodward<sup>3</sup> terms this pathologic entity "pseudopolyposis of the colon," thus distinguishing it from the colonic tumors of idiopathic origin referred to by Virchow. Since Woodward's description in 1881, many efforts to classify polyps of the colon have ended in confusing rather than clarifying the picture of this disease. Today it is recognized, however, that two general types of polyposis occur; namely, the condition first described by Wagner<sup>2</sup> and the diffuse adenoma-

tosis of Cripps.<sup>4</sup> Wesson and Barger<sup>5</sup> indicate that inflammatory mucosal tags or pseudopolyps follow such diseases as chronic ulcerative colitis, tuberculosis or severe amebiasis. Ten per cent of 1,600 cases of chronic ulcerative colitis reviewed by them presented inflammatory polyps as a sequel and 25 per cent of these might develop carcinoma, according to their statistics.

The following case is presented as one of pseudopolypsis of the colon occurring in a person with chronic, severe amebiasis and chronic ulcerative colitis:

#### REPORT OF CASE

J. O'N., an Irish nursemaid, aged 30, was seen first on Oct. 24, 1933, when she complained of "tropical dysentery." On arriving from Ireland eight years before she had severe dysentery, with bloody, mucoid liquid movements and complained of fever for a five months period. A physician demonstrated amebas in her stools one year after onset and she was given nine injections of emetine, which afforded her temporary symptomatic relief. During the next five years she had four recurrences of dysentery with fever, at which times she was treated expectantly with temporary improvement of her status.

In 1931 she was given nine treatments of emetine hypodermically and 100 pills of chiniofon, which caused nausea and vomiting but gave relief from the dysentery for a time. One

Clinical course during thirty months.

year later she had nine more injections of emetine, which were followed by dyspnea, palpitation and increased heart rate after exercise, and weakness. The intestinal symptoms cleared until two months before we saw her, since when she has had from fifteen to sixteen liquid, bloody, mucoid movements daily with cramps, but no nausea, vomiting or fever. Four months before, her hemoglobin was 28 per cent. The family history was unimportant. Ten years before, the right lobe of her thyroid was removed. Her habits were regular. Her average weight was 125 pounds (57 Kg.) but at the examination she weighed 115 pounds (52 Kg.), the loss occurring during the past four months.

On examination she was afebrile and pale, with a slightly subicteric tint to the mucous membranes and skin. The left lobe of the thyroid was fuller than the right. The area of cardiac dullness was increased to the left and the heart sounds were of fair quality, with a systolic murmur at the apical and aortic areas. The pulse was regular, with a rate of 90. The blood pressure was 112 mm. of mercury systolic, 60 diastolic. The abdomen was distended with palpable masses in both lower quadrants and was tender in the sigmoid area. The liver edge was felt at the costal margin.

Laboratory tests revealed 1,940,000 red cells, hemoglobin 28 per cent (Sahli), 4.4 Gm. per hundred cubic centimeters, and 8,760 white cells, with 67 per cent neutrophils, 20 per cent lymphocytes, 8 per cent eosinophils, 3 per cent monocytes and

2 per cent megalocytic neutrophils. The urine was normal. *Endamoeba histolytica* (motile) was demonstrated in the stool in smears stained with iron hematoxylin. Culture of the stool was negative for bacilli of the typhoid-dysentery group. Blood agglutinations were negative. The basal metabolic rate was minus 12 per cent. An electrocardiographic tracing<sup>6</sup> showed a rate of 93, slight SA tachycardia, a PR interval of 0.24 second, latent partial auriculoventricular block, and an abnormal lead 4, suggesting cardiac abnormality.

Our diagnosis at this time was:

1. Amebiasis, with colitis, dysentery and secondary anemia.
2. Myocardial damage, due to excessive emetine therapy.

Her progress during the thirty-three months that she has been under our care is outlined in the accompanying chart. The patient harbored *Endamoeba histolytica* for the first eight months of this period, but thereafter no amebas were seen on repeated examination of the stools. Thirty grams of carbarsone was given orally and 10 Gm. instilled rectally, and 30 Gm. of vinform was administered. In addition, soluble iron salts were prescribed throughout and a smooth diet high in protein. Solution liver extract-Lilly was given on two occasions intramuscularly, 100 cc. in divided amounts each time. Roentgen examination was delayed until June 24, 1935, because of the patient's financial status. When severe dysentery recurred, however, and the patient lost 20 pounds (9 Kg.) in three months without exhibiting amebas in her stools, other causes of her symptoms were searched for. Sigmoidoscopic examinations from the beginning showed an ulceration of the lower bowel which was characteristic for chronic amebiasis but which failed to clear under specific therapy. Roentgen examination of the bowel by means of a barium sulfate enema<sup>7</sup> revealed marked spasticity of the entire colon with multiple polypi, most marked in the descending and transverse colon. Since the patient was a very poor operative risk and refused surgical care, we resorted to roentgen treatment as a palliative measure. She had a total of 1,100 roentgens from June 25 to July 29, 1935, but became so weakened by the increasing dysentery and decreasing hemoglobin (it fell to the original level of 4.4 Gm. per hundred cubic centimeters) that she finally consented to an exploratory laparotomy. Two transfusions of 500 cc. were given before operation, which increased the hemoglobin from 7.8 Gm. per hundred cubic centimeters and red cells 2,140,000, to hemoglobin 9.0 Gm. and red cells 3,700,000. The white count was 5,200 cells, with 73 per cent neutrophils and 5 per cent eosinophils.

Operation was performed Aug. 20, 1935, from 10:45 to 11:22 a. m., by Dr. Weeks. Nitrous oxide and ether anesthesia was used. A low left paramedian incision was made through the skin and a very small amount of subcutaneous tissue. The abdomen was opened without difficulty. The colon was immediately visualized and palpated. At about 5 cm. distal to the ileocecal valve the intestine was contracted and hard. The serosa was granular and wrinkled and had lost entirely its customary sheen. On palpation the colon appeared hard, rubbery and firm, calling to mind the feel of a much used garden hose. This condition obtained throughout the entire colon to the rectum, only the head of the cecum appearing normal. On account of the extensive involvement of the entire colon, ileosigmoidostomy was not possible as had been planned, and accordingly a loop of ileum was brought out through a stab wound in the right flank and sutured to the abdominal wall. The abdomen was closed in the usual manner. The patient absorbed 1,500 cc. of saline solution subcutaneously during the operation.

After this preliminary operation the patient was allowed to convalesce for about five months, during which time she was at rest in bed. She received frequent 500 cc. transfusions during this time. Dilute solutions of potassium permanganate or acriflavine hydrochloride were employed in washing out the lower part of the bowel. The patient showed marked clinical improvement but failed to gain weight. Since we had roentgen evidence of polyposis of the bowel and since we believed that malignant change might occur<sup>8</sup> in the polypoid masses, we

strongly advised complete colectomy. She finally agreed to undergo this rather formidable operation, which proved to be a life-saving procedure.

The operation was performed Jan. 21, 1936, from 8:43 to 10:25 a. m., by Dr. Delprat. A long left rectus incision was made through the previous operative scar. The abdomen was opened without difficulty. There were no adhesions to the abdominal wall from the operation in August. The entire colon was palpated and found to have remained exactly as noted at the previous operation. The colon however appeared movable and not bound down, so that colectomy appeared feasible. Accordingly the cecum was drawn toward the wound and the distal loop of the previous ileostomy was divided and closed. The lateral attachments of the ascending and descending colon were divided, allowing excellent mobility. The omentum was separated from the anterior surface of the transverse colon, following which the entire colon was removed down to the sigmoid, the mesentery being ligated. This procedure was accomplished without difficulty, but in separating the lower rectum from the sacrum a large perforation was produced through the abdominal intestine and considerable soiling of the peritoneum followed. The intestine therefore was merely loosened as far down as possible and then cut across with scissors. The peritoneum was closed over it as in the method of Coffey, with intraperitoneal and extraperitoneal drainage. The patient was then placed on her side and the remainder of the rectum and anus removed from below, the cavity being packed with gauze soaked with potassium permanganate solution. Following the operation, while the patient was still on the table, she was given 500 cc. of whole blood.

Pathologic examination of the entire colon by Dr. W. P. Stowe showed reddened, hemorrhagic areas, with discrete ulcerations and multiple areas of polypoid excrescences of granulation tissue, none of which exceeded a centimeter in height or width. Microscopic sections showed lymphoid hyperplasia in the mucosal and submucosal coats, increased numbers of eosinophils, plasma cells, and round cells with some polynuclear cells between and beneath the glands. In some sections, islands of round cells and eosinophils were seen extending into the muscularis zone. The glands showed no evidence of malignant change, but superficial ulceration and necrosis were seen frequently in the crests and in the cryptlike folds of mucosa. Polypoid outgrowths of the adenomatous type were not seen.

Several ulcerated areas of the colon were sectioned and the tissue was stained with iron hematoxylin and searched carefully for amebas, but none were demonstrated.<sup>9</sup>

For fourteen days following the operation the patient's temperature did not exceed 37.5 C. (99.5 F.). Her pulse varied, however, from 120 to 140 for sixteen days, thereafter gradually returning to normal. This might be expected because of the soiling at operation. The entire abdominal wound became infected and broke open to the peritoneum. Secondary suture was not possible because of the adjacent discharge ileostomy, so that approximation of the wound edges with adhesive plaster seemed advisable, although unsatisfactory on account of the patient's abdomen being scaphoid at all times. Under treatment with gentian violet solution, however, the wound gradually filled in and was entirely healed on her discharge from the hospital on April 4, 1936.

Since leaving the hospital the patient has gained rapidly in strength, weight and hemoglobin level. When last seen (July 22, six months after colectomy) she was symptom free, her abdominal wound was entirely healed, she averaged two evacuations daily, her weight was 54 Kg. and her hemoglobin was 13.6 Gm. per hundred cubic centimeters, with 4,270,000 red cells and 8,240 white cells, with a normal differential count.

#### SUMMARY

Pseudopolyposis of the colon occurred in a patient successfully treated for amebiasis but unsuccessfully treated for coexisting chronic ulcerative colitis. Colectomy proved a life-saving measure in spite of the patient's extreme debilitation, emetine poisoning and anemia due to eight years of chronic, severe dysentery.

## Special Article

### THE PHARMACOPEIA AND THE PHYSICIAN

#### THE USE OF ANTISYPHILITIC REMEDIES

H. N. COLE, M.D.

CLEVELAND

*This is one of a series of articles written by eminent clinicians for the purpose of extending information concerning the official medicines. The twenty-four articles in this series have been planned and developed through the cooperation of the U. S. Pharmacopeial Committee of Revision and THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.—ED.*

In syphilis there is an active, motile organism which requires moisture and tissue for its further spread and vitality. It is well known that *Spirochaeta pallida* dies within one-half hour if exposed on a dry surface; e. g., a glass slide. On the other hand, if anywhere on the body the organism gains entrance into the skin, through a bruise, a cut or a crack, an infection will probably occur. Of this there is not absolute surety, for it is possible that certain individuals may have some resistance to the disease, perhaps enough at least to ward off an isolated contact. If the organism does penetrate the skin and multiply, the spread is probably quite rapid. One can remember the time when it was considered good therapy to excise the chancre. Now it is felt that there is extension to the draining lymph nodes within a few hours, and probably some of the spirochetes are to be found in the heart blood within a matter of a day or a few days at the most. The multiplying organisms at the site of penetration of the skin finally set up an immune reaction on the part of the host consisting of an infiltrate of serum of mononuclear elements and of fibroblasts; this is spoken of as the chancre or the primary lesion.

The multiplying organisms spreading through the draining lymph chains set up a characteristic, sharply defined, indurated, painless, enlarged type of node with satellite, smaller nodes around it. The syphilitic nodes do not fuse together. They are quite movable and, unless secondarily infected, do not break down. Through the lymph channels and blood stream there is an early further spread of the infection to other parts of the body, notable to the ectodermal elements, resulting in an eventual further immune reaction on the part of the host anywhere from eight to twelve weeks after the infection, known as the secondary stage or eruption. It appears first on mucous membranes and shortly thereafter on the skin. It is also found on the walls of the bladder, on the viscous surfaces and on the meninges. The eruption may be profuse or sparse. There is still difference of opinion as to the amount of relationship between the amount of eruption and the intensity of the disease. There is also recognized the so-called symptomless infection in which the primary lesion and the secondary changes may have been absent or so evanescent that the first intimation the patient may have of an old syphilis may be a positive blood Wassermann reaction, a tabes dorsalis, an aneurysm or a mysterious devastating ulceration of the skin. Sooner

From the Department of Dermatology and Syphilology, Western Reserve University School of Medicine.

or later, the secondary manifestations of the disease gradually disappear as the result of treatment or as the result of an increasing amount of immune bodies being built on the part of the host. With occasional later flare-ups the disease gradually drifts into a further stage of latency, in which physical examination may reveal no symptoms of the syphilis and it can be diagnosed only by the history and by a serologic examination. This period of dangerous silence may last for years. It is the period of time in which organisms deposited in the lymph nodes and in the tissues cause chronic fibrotic changes with endarteritis, which may eventually result in a frank aortitis, in a meningo-arteritis, in a hepatitis, or in a gumma of the skin or bone. For some of these changes there may be an exciting cause—trauma. For aortitis, race may play a part; e. g., the Negro. For some there may be no explanation. It is certain that the central nervous system process, e. g., tabes or dementia paralytica, or the insidious aortitis, are laid down early in the course of the disease by deposition of the organism in the vasa vasorum. The central nervous system syphilis is not a change developing "out of the blue" ten or fifteen years after the infection. The syphilitic person who has had little or no treatment may well have developed a basilar meningitis secondary to an infection of the vasa vasorum or thereby the beginnings of a later tabes or dementia paralytica may have been laid down. Moreover, the aortic insufficiency or the aneurysm is an early rather than a late concomitant of an untreated or poorly treated syphilitic disease, allowing specific changes to take place in the vasa vasorum which eventually cause weakening of the vessel walls, scar formation and retraction of the aortic leaflets.

#### PUBLIC HEALTH RESPONSIBILITY IN SYPHILIS

Given a case of syphilis in its early stages, there is a heavy public health responsibility on the part of the physician. All contacts in the home should be repeatedly checked, especially in case the patient is married. Moreover, even in this day and age it may be necessary to examine conditions in the patient's place of business. I was recently consulted by a man with a chancre of the lip and was amazed to find that a common drinking cup was being used in his manufacturing plant, where several hundred men were at work. In all cases of early syphilis, all contacts should be carefully checked by the physician. It may mean the prevention of numerous transfers of the disease to innocent persons. With a preventable disease such as syphilis the medical profession does not exercise sufficient care in diagnosing the disease, in picking it out in its daily work and in properly handling its various manifestations. How many physicians bother about routine Wassermann tests on their patients? And yet many puzzling complaints or signs will be revealed by this single act. It is true that around 30 per cent of all syphilis is latent in character—to be recovered only by careful questioning and positive serologic reactions. And yet it is this 30 per cent of patients who may, in part, be the spreaders of new infections through relapses or act as transfer agents of the disease to the next generation through pregnancy. Moreover, a certain number of them may even then be developing an aortitis or a dementia paralytica. From 25 to 30 per cent of the inmates in asylums are suffering from syphilis, poorly treated or never treated. The Cooperative Clinical Group,<sup>1</sup> in

a recent study of cardiovascular syphilis, found that 69 per cent of the patients had never had any treatment for syphilis. This should indicate to physicians the necessity of more careful examinations of the patients, including routine Wassermann tests. When syphilis is discovered, its thorough treatment is paramount. The medical man is surely in the Court of Public Opinion with regard to this situation, and if it is not properly met the state will next step in and assume full responsibility for handling this disease.

#### RESULTS DERIVED FROM ANTISYPHILITIC DRUGS

In considering a drug worthy of trial in the treatment of syphilis, several criteria are to be considered:

1. The drug should be cheap enough to be available to all.

2. It should be in as simple a form as is possible, not requiring a too elaborate technic for its administration. Because of this criticism our most potent antisiphilitic remedy, arsphenamine, is rarely employed outside syphilis clinics and hospitals. Neoarsphenamine is more easily administered.

3. The remedy should be free from attendant unpleasant symptoms, such as pain, nausea, emesis and headache. Moreover, severe systemic after-effects should not follow its use.

4. Its action should be relatively rapid in alleviating acute symptoms of syphilis; thus, a remedy requiring more than a few days to destroy the spirochetes on moist papules on the lips is not sufficiently potent.

5. The summum bonum in the antisiphilitic drug is the preparation that at one dose will destroy all the organisms of the disease in the body without attendant harm to the host. This was Ehrlich's idea when he announced his six hundred and sixth trial compound. Unfortunately, it failed to satisfy the requirement. So we are now forced to rely on the drugs that will come closest to this desired result without too severe reaction to the host. Experience has shown that the three heavy metals in their proper salts—arsenic, bismuth and mercury—best answer these fulfillments. The efficiency of the respective metallic salts has been worked out through studying the rapidity of the disappearance of *Spirochaeta pallida* from inoculation chancres of rabbit testes.

Investigations have also been made on the rapidity of disappearance of trypanosomes from infected mice and rats. With the arsenicals this trypanocidal activity corresponds quite well with the treponemicidal rate, but unfortunately with bismuth compounds this is not the case.

As a definite ratio of the effect of a drug against the spirochetes, one employs what is known as the therapeutic ratio—the maximal tolerated dose over the minimal effective dose. From microscopic study of the rapidity of disappearance of spirochetes after heavy metal therapy from inoculation chancres in rabbit testes, and through transplants to further rabbit testes of the infected testicular material it has been possible to work out the therapeutic ratio. Thus, arsphenamine has a ratio of from 20:1 to 30:1.

It is true that the mistake must not be made of too closely comparing rabbit syphilis to human syphilis. It is well known that rabbit syphilis may actually be eradicated from the host; with the human variety this is certainly not such an easy proposition. The chemotherapeutic ratio for potent bismuth preparations runs around 50:1 or more when the drug is used intramuseally. Bismuth is ten times as toxic if used intra-

1. Cole, H. N., Usilton, Lida J., and others: *Deliberations Eleventh International Dermatological Congress, Budapest, Patria, 1935*, p. 430.

venously and should never be employed by that route. With mercury the chemotherapeutic ratio is only 1:1 or 1:2. Thus it is easily understood why the trend of syphilis therapy has been more and more to arsenical and bismuth salts.

#### ACTION OF THE HEAVY METALS IN SYPHILIS

It is hardly the scope of this short article to consider the mode of action of the heavy metals against syphilis. This has been taken up at length in various publications both here and abroad. It is known that a mercury salt rubbed into a chancre swarming with spirochetes causes them to disappear. Yet the dosage of mercury *in vitro* sufficiently large to destroy the organisms, if used in life, would kill the host as well. It is probable with all three of these metals that the action is, in part, a specific one but also has some effect on the body cells that enables them, in turn, to overwhelm the spirochetes. Probably the arsphenamines when injected are transformed in the body into a more potent form, arsenoxide, before they exercise their effect, and Levaditi thinks that the bismuth salts are activated by extracts of the tissues into a much more active compound, which he terms "bismoxyl."

#### PREFERRED MODE OF ATTACK IN TREATING SYPHILIS

The elder Fournier was considered to be one of the greatest syphilologists of his time, and no doubt he did much to spread knowledge of syphilis. Moreover, he was one of the earliest adherents to the theory that tabes dorsalis was due to syphilis. This was long before any specific organism had been discovered.

However, the intermittent treatment for syphilis that he so strenuously practiced and advocated undoubtedly impeded the advance of syphilis therapy for many years. In fact, even today, as a result of his teaching, some very able men still employ an intermittent mode of attack in handling this disease. Fournier went on the theory that the physician using mercury was employing a potent remedy, toxic to the liver, bones and gastro-intestinal tract, but especially so to the kidneys. Therefore the patient undergoing treatment should take mercurials for a time, alternating these courses with purposeful rest periods. Such a form of treatment was kept up for from three to four years, the length of the rest periods being gradually increased and the courses of treatment being decreased. It is true that Fournier did not have the additional more potent heavy metals bismuth and arsenic to aid him in his work.

It is to the credit of Almkvist in Europe and almost simultaneously to the credit of Keidel and Moore in this country that attention was called to the disadvantages of the intermittent treatment of syphilis. If it were possible to give syphilitic patients large enough doses of arsphenamine and other heavy metals to cure them in one course of treatment there probably would be no schema necessary in treating syphilis. However, it must be realized that in syphilis one is dealing with a chronic infection due to an organism that, with our present remedies, disappears only gradually from the lymph nodes, skin and deeper structures. In fact, some men, like the late Dr. Warthin, claimed that they never entirely disappear; rather, that the disease is merely "arrested." At any rate, it is quite evident that in a situation comparable to this it would theoretically be unwise to treat the patient by an intermittent form of therapy. Grant that the organisms were checked by

the arsenicals, the bismuth or even the mercury, would it not then stand to reason, if purposeful rest periods were instituted in the course of treatment, that during these periods, with the effect of the remedies removed, any viable organisms would once more start multiplying? Not only does this theoretically sound tangible, but in actual practice the writings of Moore and of the Cooperative Clinical Group would indicate its actual probability. And a recent report by Stokes of the League of Nations investigations comparing the results of the Cooperative Clinical Group, using the continuous system of treatment of syphilis as against the intermittent form of treatment employed by some of the large European clinics, revealed a very favorable comparison for continuous treatment.

Instead of giving the patient purposeful rest periods after a course of arsphenamine or preparations of bismuth or mercury, the treatment is alternated. Perhaps the patient with an early syphilis receives a course of arsenical injections, which is followed at once by a course of intramuscular injections of a bismuth compound. This in turn is followed by another course of arsenical treatment. In this manner, by alternating the drugs, one keeps the disease under continuous attacks with some form or other of antisymphilitic therapy.

Moreover, there is another very important argument in favor of continuous treatment; viz, the problem of relapse in syphilis. In the Cooperative Clinical Group Studies,<sup>2</sup> it was found that relapses as a rule came early in the course of syphilis. In the group material 25 per cent came in the first six months after infection, and by the end of the second year 85 per cent of the relapses to occur had intervened. The average time of relapse was eighteen months after infection and it occurred as a rule nine months after the last treatment. In other words, a physician treating an early case of syphilis should follow the patient carefully during the first two years of the disease, as this is the critical period for relapse to appear. This has been the bugaboo not only of the family physician but also of the syphilologist in treating syphilis. The patient with an early syphilis has been put on antisymphilitic therapy, has done nicely for a time, and all at once, on returning from his purposeful vacation period, is found to have a relapse of his Wassermann test to positive; or, again, he has returned with severe headaches, a lumbar puncture is done and he is found to be suffering from syphilitic meningitis. Perhaps he returns with a type of lesion even more dangerous to the public and to his family—the infectious relapse, in the form of a moist papule on his lip or with condylomata lata of the genitalia or rectum. The Cooperative Clinical Group found that relapses of all kinds, including Wassermann fastness, were much lower if continuous therapy had been employed, 13 per cent as against 21 per cent with intermittent therapy. Moreover, if irregular, haphazard treatment was used, the percentage of relapses mounted to 45. Finally, if the intensive form of therapy was employed, consisting of three or four daily maximal doses of arsphenamine followed by a series of heavy metal injections and purposeful rest periods, the percentage of relapses again was high, 41.

That intermittent treatment, with its vacation periods, is bad can be seen from still another angle. The Wassermann reaction in the earliest stage of the syphilitic chancre, up to ten or twenty or more days, is not

2. Stokes, J. H., and others: *Compt. rend. des. séances, VIII Congr. internat. de dermat. et de syph.*, Copenhagen, 1930, p. 768.

revealed in the syphilitic patient's blood. This is known in syphilologic parlance as the seronegative phase of the disease. It is the most favorable time in which to institute therapy, diagnosis being made on the primary lesion by means of the darkfield illuminator or by study of smears made from the serum of the chancre and appropriately stained with Wright's, Giemsa's or Fontana's stains. As sufficient reacting bodies to the disease are built up in the blood stream, the Wassermann reaction changes from negative to positive. Ordinarily this takes place at from fifteen to thirty days after the inception of the infection, depending on various circumstances. This stage of the disease is spoken of as the seropositive stage and really is little different from the secondary stage of syphilis. Without therapy this positive reaction on the blood remains for some years, after which a negative Wassermann reaction may gradually develop in a certain number of cases. Certain phases of late syphilis are more prone to a positive Wassermann than others; e. g., dementia paralytica, in which one encounters around 90 per cent of positive reactions. With tabes, and especially with Charcot's joints, on the other hand, the percentage of negative reactions may reach as high as from 30 to 40. It is unfortunately true that the Wassermann reaction is the "sine qua non" to all too many physicians and that as long as the Wassermann reaction is positive treatment is indicated. While this is many times a mistake, yet a persistently positive reaction with no reversal to negative in the experience of the Cooperative Clinical Group was seen much more frequently when intermittent treatment was employed. In fact, with continuous therapy there was reversal of the reaction to negative in 82 per cent of the cases, as contrasted with but 37 per cent in which intermittent treatment with purposeful rest periods was employed. And with aimless, irregular treatment such as the patient all too often takes into his own hands there were but 5 per cent of Wassermann reversals. Undoubtedly most of the persisting positive blood Wassermann reactions in early syphilis can be laid at the door of purposeful rest periods in the course of treatment, thus allowing the spirochetes in the body to start multiplying once more and build up new foci of disease. The general waging a vigorous campaign against the enemy allows no respite, no breathing spells. The same policy should apply when the physician takes on himself the great responsibility of handling a case of early syphilis. If the victory is not won in the first two years, it is going to be a long campaign. Undoubtedly the rest periods offer opportunity for the laying down on syphilitic cardiovascular disease of central nervous system involvement and the like.

The amount of treatment administered also has a great bearing on the factor of relapse. In the Cooperative Clinical Group material, of those patients receiving twenty or more arsenical treatments with interim heavy metal, only 12 per cent had an infectious relapse, while, on the other hand, 64 per cent of the patients receiving but one to four injections of an arsenical with interim heavy metal had relapsed, while if even five to nine were given, but one-seventh as many patients relapsed. And in connection with syphilis of the central nervous system three times as many neurorecurrences developed if less than twenty injections of an arsenical with interim heavy metal were employed as when more than twenty were employed. Indeed from a study of relapses seen in the group material it was possible to draw the deduction that adequate treatment of at least

twenty to thirty injections of an arsenical and interim heavy metal in a case of early syphilis gave best promise of the patient's immune powers being supported and not broken down.

#### SYSTEMIC REACTIONS FROM ANTI-SYPHILITIC DRUGS

Before discussing the suggested outlines of treatment for various phases of syphilis, it may be well to devote a few words to systemic reactions observed from the drugs used. This is all the more important if one endeavors to follow more or less of a routine, especially in early syphilis.

Mercury is used less and less today, so that it is only necessary to recommend careful supervision of the kidneys in all patients taking mercurial preparations. Gastro-intestinal reactions in the form of diarrhea or bloody diarrhea, the patient himself will note. Fortunately the severe cases of mercurial stomatitis, even with ulceration, are rarely seen today.

With both bismuth compounds and arsenicals the kidneys are not so liable to be affected. Nevertheless, it is good practice with any patient under heavy metal therapy to examine the urine for albumin and red cells at every visit.

The patient undergoing treatment with heavy metals should be questioned at each visit as to any unforeseen happening following the last treatment. Gastro-intestinal reactions, itching of the skin, sores in the mouth, headaches, blurring of vision, may all be very significant. The gastro-intestinal reactions are usually the result of the arsenicals. If they persist with succeeding injections, despite abstinence from meals, it may require change of remedy. Occasionally the use of a tablet of Atropine Sulfate  $\frac{1}{100}$  grain (0.0006 Gm.) one-half hour before the injection may obviate the reaction. Or if the patient develops a nitritoid reaction at the time of the administration of the arsenical, an intramuscular injection of Epinephrine, from 0.3 to 0.5 cc. of a 1:1,000 solution, will be of great value. Itching of the skin or any cutaneous reaction following bismuth, but especially arsenical therapy, should be the signal for careful check up of the causation. The best treatment of heavy metal reactions in syphilis therapy is prophylaxis. Telltale bluish lines on the gums are seen after bismuth, and one may even observe ulcerations in advanced cases. Severe headaches and puzzling "grip-like" attacks are occasionally seen after bismuth injections, though they are rarely recognized. Blurring of vision may be encountered after tryparsamide therapy of central nervous system syphilis. No patient should receive this drug until his visual and color fields have been carefully checked. Contracted fields are probably a contraindication to this form of therapy and any patient complaining of visual disturbances following tryparsamide should, for the time, have the treatment discontinued. With severe cutaneous reactions from the arsenicals the use of emollient measures rather than of stimulating remedies will be most helpful; e. g.

#### Rose Water Ointment

	Gm. or Cc.

Some patients prefer plain Olive Oil in such a situation. Sometimes, when there is pruritus, the lotion given below will be found of value, the mercury being added to obviate folliculitis.

*Lotion of Phenylmercuric Nitrate and Tannic Acid*

	Gm. or Cc.
R Phenyl Mercuric Nitrate.....	0.018
Glycerite of Tannic Acid.....	45.0
Hamamelis Water .....	ad 180.0

Misce. Signa: Apply locally as required.

Certain patients with a generalized infected dermatitis exfoliativa will get much relief from the use of hot potassium permanganate baths in a dilution of 1:5,000.

Many times, in patients suffering from the foregoing chronic condition, the use of Solution of Liver, either by mouth in doses of one teaspoonful, three times a day in orange juice, or of intramuscular injections of Purified Solution of Liver, 2 cc. every two or three days, may be very helpful in starting a turn for the better.

Rarely, fortunately, does the physician encounter an arsenical hemorrhagic encephalitis. It generally comes after but two or three injections and is initiated with high fever, headache, muscular twitchings and convulsions. Lumbar puncture should be performed at once to relieve pressure, and venesection may be of value. Here again intravenous injections of Sodium Thio-sulfate 15 grains (1 Gm.) should be given once or twice a day for a few days if the patient survives that long. I have seen a patient already unconscious and having convulsions from this condition return to consciousness following a slow subcutaneous hypodermoclysis of 5 per cent dextrose, 500 cc. It may be repeated in three hours.

Hemorrhagic reactions following the use of the heavy metals should be the signal for their instant and probably permanent discontinuance. These reactions seem to be more frequent after the use of sulfarsphenamine, so much so that many syphilologists have discontinued its use. Blood dyscrasias have been seen after both bismuth compounds and arsenicals, and a routine white blood count, differential and platelet count should probably be done on every patient undergoing antisyphilitic therapy every two months, and in hospital practice this should be feasible every month.

With a granulocytopenia the first indication may be an acute deep ulceration in the throat. Transfusion is indicated, and pentnucleotide-N. N. R. may be tried, a 10 cc. vial injected intragluteally twice a day until the white blood cell count has definitely risen and thereafter once a day until the count has been normal for at least three days. Sodium Thiosulfate should also be used in 1 Gm. doses intramuscularly every day along with the same remedy by mouth in like doses of keratin coated capsules three times a day.

The appearance of icterus in the course of arsenical therapy is most disturbing. While syphilitic hepatitis is rare, it may occur, especially in an irregularly treated patient, or in a patient given purposeful rest periods. At times it is difficult to distinguish between a catarrhal icterus and an arsenical type. Probably all patients with icterus should have arsenicals discontinued for the time being, and if an arsenical process is finally diagnosed the patient should be treated with bismuth and mercury compounds in the future. Diet, elimination and Sodium Thiosulfate is indicated in such cases. Hypodermoclysis of 5 per cent dextrose solution may be of value. While not entirely convinced, I would

recommend in a severe case the trial of decholin sodium N. N. R. intravenously, 5 or 10 cc. of the 20 per cent solution. A second and third injection of 10 cc. may be given on the succeeding two days, followed by decholin by mouth, from 0.25 to 0.5 Gm. (4 to 8 grains), two or three times a day after meals for several weeks.

The physician treating the syphilitic patient should be constantly on the lookout for unusual or unforeseen symptoms. These should be signals to discontinue treatment until the causation is explained. There is nothing more inexcusable than to see a severe generalized exfoliating dermatitis in a case in which the physician has given another dose of an arsenical after the telltale eruption has already appeared. Prophylaxis, prevention, is the watchword in using heavy metals for syphilis.

TREATMENT OF SERONEGATIVE AND SEROPOSITIVE AND SECONDARY SYPHILIS

It should be understood that in attempting an outline of treatment for early syphilis that there are bound to be exceptions. Such an outline is given with the hope of furnishing an ideal for treatment in terms of present day knowledge. Many times it cannot be carried out. Perhaps the patient is susceptible to arsenical therapy, or it may be that he develops symptoms of kidney irritation after the use of the other heavy metals, or again he may be one of those individuals who develop severe headaches after the use of bismuth compounds. There are bound to be such exceptions to the routine of treatment.

Again, the problem of type of arsenical to be used must be considered. Undoubtedly arsphenamine is somewhat more potent than neoarsphenamine, but it is questionable that the average physician in office practice will use the former because of its greater potency. It requires more manipulation: it also requires the use of normal sodium hydroxide, 0.85 cc. for each 0.1 Gm. of the drug. This is not always available and if in stock may be deteriorated. Consequently the average physician prefers neoarsphenamine. It is kept preferably in the icebox in the dark. The desired dosage is best sprinkled over the surface of from 8 to 10 cc. of sterile distilled cold water and then dissolved by gentle rotation of the container. The dosage is injected very slowly intravenously by means of a 10 cc. glass syringe. The injection should last at least one minute. There are far fewer reactions where the drug is injected slowly. In hospital practice and in well equipped large offices arsphenamine may be preferred, as sufficient drug for several patients may be prepared at one time. The drug is administered by the gravity method in a dilution of from 10 to 20 cc. of water for each 0.1 Gm. The intravenous injection should be delivered slowly. Stokes has called attention to "rubber tubing" reactions.

Another arsenical being employed quite extensively, and accepted by the Council on Pharmacy and Chemistry, is Mapharsen. It is administered by the intravenous route and is notable for the freedom from reactions, outside of gastro-intestinal reactions, following its use. It is employed in dosages of from 0.03 to 0.06 Gm., and the drug, after being dissolved in from 5 to 10 cc. of distilled water, is administered rapidly intravenously. If the dose is given slowly, the patient may complain of pain up the arm. In this respect, rapidity of administration, it differs from arsphenamines. Mapharsen has now been used quite extensively and seems to have found a place in the therapy of syphilis. It may be used in place of arsphenamine or

neoarsphenamine as the arsenical, especially if there is any reason why the others cannot be employed.

There are many bismuth preparations on the market, and many of them are quite efficient. It probably would be well for the physician to learn the action of but a few, well tried ones and depend on them. If a slower, but comparatively constant bismuth action is desired, one may use a suspension in oil of bismuth subsalicylate 0.13 Gm. (2 grains) intramuscularly in the buttock once a week for a course of from eight to twelve weeks, depending on circumstances.

Again, if it is desirable to get a more rapid bismuth action, one may employ one of the soluble preparations. Naturally, they will be absorbed and excreted more rapidly; hence it will require their administration two or three times a week. Such a type of therapy would be indicated more in hospital practice and perhaps when the patient is arsenic sensitive, forcing the physician to depend on preparations of bismuth and mercury to treat the disease. As intramuscular injection of Thio-bismol 0.2 Gm. (3 grains) three times a week, of Iodo-bismitol 2 cc., or of the aqueous solution, bismuth sodium tartrate, 0.03 Gm. (one-half grain) two or three times a week would be indicated. Such therapy can be continued for a series of from fifteen to eighteen injections, depending on how the patient reacts.

#### REQUIRED TREATMENT FOR A CASE OF EARLY SYPHILIS

Given an average routine case of early syphilis, treatment should be kept up in a continuous form with alternating courses of arsenicals and preparations of bismuth or perhaps of mercury for at least one year after all signs and symptoms of the disease have disappeared. Thus the Cooperative Clinical Group<sup>3</sup> has found, from a study of several thousand cases of early syphilis, that anywhere from twenty to thirty, and preferably thirty, injections of arsphenamine and approximately the same number of insoluble bismuth injections or, under certain conditions, of mercury are necessary to give a satisfactory result. Neither drug should be used in less amounts, provided the patient stands them well. Too little of the arsenical or, again, too little of the bismuth may lead to resistant Wassermann-fast cases and to various types of relapse. In beginning the treatment of an early case of syphilis it is justifiable to shorten the intervals between the first three injections of the arsenical. This is done with the hope of getting the disease more rapidly under control. Moreover, with the last injection of each course of arsphenamine it is well to give the first injection of bismuth subsalicylate; thereby there is no interval of time in which the patient is not under continuous treatment. A Wassermann test of the blood should be made at the beginning and at the end of each course of treatment. Moreover, it is well to take a second Wassermann test the first and fifth days after the first arsenical injection of succeeding courses of treatment—the provocative Wassermann reaction. Often a negative reaction may be achieved by the end of the first or second course of treatment. It is desirable to hold this status, for treatment must be kept up for one year after all signs and symptoms have disappeared. A lumbar puncture should be done early in the course of the disease; otherwise a central nervous system involvement may be submerged temporarily by treatment. If it is negative, another should be

performed before the therapy is discontinued at the end of eighteen months or two years. If, under continuous therapy, there is a return to a positive Wassermann reaction on the blood, early cardiovascular or central nervous system involvement should be ruled out. It must be remembered that an occasional patient will relapse no matter what is done for him; fortunately these cases are not common.

A careful routine physical examination should be made of the patient on starting therapy and repeated at least once a year thereafter. Moreover, after treatment is discontinued there should be a careful neurologic examination and fluoroscopic examination of the cardiovascular stripe. For several years after therapy is discontinued the patient should have a Wassermann test every six months and thereafter once a year, along with the routine physical examination that every individual should receive.

#### Solution of Potassium or Sodium Iodide

℞ Potassium or sodium iodide.....	Gm. or Cc.
Distilled Water.....	aa 100.0
Misce. Signa: 10 to 20 drops in water after meals.	

The place of potassium iodide or sodium iodide in the treatment of syphilis is still debatable. There is no question of its value in late syphilis and where it is desired to achieve a breaking down of the connective tissue barriers of syphilomas. The drug is of value in syphilitic meningitis in even larger doses and it should probably be prescribed with the courses of heavy metals even in early syphilis.

For purposes of convenience, a chart modified from the Cooperative Clinical Group Studies<sup>4</sup> is appended. It is noted that the therapy for seropositive primary and secondary syphilis is somewhat longer than for seronegative primary disease. The bismuth employed should be of a type that will furnish from 0.080 to 0.12 mg. of metallic bismuth at a weekly injection; thus it limits itself to either a liposoluble preparation or to an oil suspension if but a single weekly injection is employed.

#### LATENT SYPHILIS

One of the most important phases of syphilis is the so-called latent syphilis. It is that period in which it is impossible to make a diagnosis of the disease except through a clear cut history and a positive blood Wassermann reaction; in fact, many times even the history is not obtainable. A case showing spinal fluid changes but no pathologic condition on physical examination would be classed not as latent syphilis but as symptomless syphilis of the central nervous system. These latent cases are important, as in this period a submerged syphilis may be silently preparing the way for more active symptoms; e. g., of the aorta or of the central nervous system. Moreover, they may be important from a public health aspect through danger of infectious relapse or, in the female, transmissal to the next generation through pregnancy. Probably 30 per cent of all syphilis is in the latent stage and demonstrates too well the urgent routine use of the Wassermann test on all new patients consulting the physician. With latent syphilis, as Moore<sup>5</sup> well puts it, "the aim of treatment is no longer radical but instead clinical arrest and the prevention of infection to others." Thus the outline already given may be modified slightly to con-

5. Moore, J. E., and others: The Treatment of Latent Syphilis, Ven. Dis. Inform. 13:317 (Aug.), 351 (Sept.), 371 (Oct.), 389 (Nov.), 407 (Dec.) 1932, 14:1 (Jan.) 1933.

sist of ten weekly injections of nearsphenamine followed by ten weekly injections of bismuth subsalicylate, each 0.2 Gm., the foregoing being alternately used up to a total of thirty injections of each. Sodium or potassium iodide is indicated the first year along with the heavy metal courses and in the second year between the courses of heavy metals.

In the second year three ten injection series of bismuth salicylate may be given, a rest period of ten weeks being allowed between the injections. Daily injections of Strong Mercurial Ointment 4 Gm. may be employed in place of the bismuth subsalicylate during the second year, from fifty to sixty rubs being considered a course of treatment.

The necessity of continuous therapy is not so urgent after the first year of the disease, as the patient's own immunity is probably built up to a certain extent. Following the period of treatment, whether the blood Wassermann reaction is positive or negative, it would be well to follow the patient yearly with complete physical examination and laboratory check up. This is the type of patient who all too often, because of a positive blood Wassermann reaction and nothing else, is treated on and on ad infinitum.

This type of treatment may be suitable for late tertiary syphilis of the skin and bones, provided there is no involvement of the cardiovascular system. Potassium or sodium iodide is indicated at once in all later stages of syphilis for the purpose of absorbing connective tissue walls around syphilitic foci. In such a case it might be well even to continue the heavy metal therapy with rest intervals over a further period of one year.

#### CARDIOVASCULAR SYPHILIS

The medical profession is now beginning to realize that cardiovascular syphilis is one of the commonest and severest complications of late syphilis. Moreover, a recent survey by the Cooperative Clinical Group has shown that 62 per cent of the patients with uncomplicated syphilitic aortitis, 76 per cent of those with aortic regurgitation and 84 per cent of the group aortitis with sacculated aneurysm had been previously untreated for their syphilis. On the other hand, in a series of cases followed from three to twenty years, none of the patients developed aortic regurgitation or aneurysm provided they had been adequately and regularly treated during the early stages of syphilis. It is thus evident that the best treatment of cardiovascular syphilis is prophylactic, thorough, continuous treatment of the early disease. On the other hand, once the disease is established, much will depend on the condition found. Bed rest may be necessary for a time, and in the presence of cardiac breakdown pulverized digitalis 0.1 Gm. is indicated. Patients with edema may also be benefited by the diuretic action of the heavy metal salts; e. g., bismuth sodium tartrate 0.03 Gm., iodobismutol 2 cc., thiobismol 0.2 Gm. or mercuric succinimide 0.015 Gm., injected intragluteally three times a week. Certain patients will be unable to stand any arsenical and the physician must depend on preparations of mercury, bismuth and the iodides. Some patients, however, are much benefited by their cautious use. After a preliminary course of either mercury or bismuth compounds to prevent therapeutic shock, the patient may be started very cautiously on nearsphenamine 0.05 to 0.1 Gm., gradually increased to a maximum dose of from 0.2 to 0.45 Gm. given to a maximum of ten to twelve weekly doses. Better results are achieved with smaller doses. In all cases, reactions of any type must be prevented in order to

relieve strain on an already overburdened myocardium. Between succeeding courses of nearsphenamine, courses of insoluble bismuth oil suspensions may be employed, e. g., bismuth subsalicylate, with good response. Alternating courses of the aforementioned drugs may be kept up for at least two years. Vigorous treatment must be avoided at all costs, and, naturally, every

patient with cardiovascular syphilis should be kept under close observation, treated according to symptomatology, and, if possible, given a certain amount of treatment throughout life.

#### SYPHILIS OF THE CENTRAL NERVOUS SYSTEM

The scope of this article will not allow anything more than a cursory review of which is considered good treatment for syphilis of the central nervous system. With early involvement of the central nervous system, a schema of treatment such as that suggested for early syphilis may be adopted, with the deletion of the first three doses of the arsenical in a space of ten days, the

doses being given once a week. Moore believes in the use of full doses of 0.75 Gm. of neoarsphenamine or 0.5 Gm. of arsphenamine in these cases. The treatment should be continuous, with alternating courses of arsenicals and preparations of bismuth. In case the process is of a vascular type or of a meningitic character, it may be well to hospitalize the patient and give a preliminary course of soluble heavy metal injections; e. g., iodobismutol 2 cc. or bismuth sodium tartrate 2 cc. twice a week for from eighteen to twenty-four injections, or of thiobismol 2 cc. three times a week for the same number of treatments. Naturally, potassium iodide or sodium iodide is indicated in such cases. Some men believe in the use of large doses; whether more will be achieved from enormous doses than from 1 to 3 Gm. three times a day is a question. In all syphilis of the central nervous system the effect of specific therapy should first be tried. Moreover, one is dealing with a disease due to an organism that is best met with such specific measures. The progress of the disease can be reviewed by the Wassermann reaction at the end of each course of treatment and by the lumbar puncture done every six months up to three or four times a year. More and more however the consensus is turning to the use of nonspecific therapy in all resistant syphilis of the central nervous system. Consequently, if after a year of treatment there has not been much response, a course of preferably malaria is to be recommended. In a recent comparison by Epstein, Solomon and Kopp<sup>6</sup> of malaria and diathermy in the treatment of dementia paralytica they found malaria to be preferable. If the patient can stand the treatment, a course of from ten to twelve or fifteen chills should be given. Following this treatment I prefer a course of neoarsphenamine, eight injections, each of 0.75 Gm., as soon as the patient is in a condition to stand it. This is given with the idea of attacking any surviving organisms that can be reached with specific measures. Then following a short course of bismuth injections the patient should be given a long course of tryparsamide, starting with an intravenous injection of from 0.5 to 1 Gm. and gradually working up to a maximum weekly dose of 2.5 Gm. As a preliminary to the treatment, the eyes should be carefully examined, as to both visual and color fields. If they are within the range of normal (not contracted) limits, the patient will probably have no reaction from this drug. Nevertheless, the physician should keep in mind the danger of damage to the optic nerve. Generally the symptoms show up within two or three weeks, with blurring and feathering of vision. In such a case treatment should be stopped for a week or more and later cautiously resumed. Often the therapy is continued up to a total of forty or fifty injections.

The patient with syphilis of the central nervous system is a problem in himself. It is difficult more than to outline the measures to be tried in such cases. A fair proportion will respond to the technic described; many will be resistant. On the other hand, there comes to mind a vascular central nervous system syphilis in a man aged 50, seen fifteen years ago, who never had anything except courses of injections of mercuric salicylate 0.09 Gm. intragluteally every week, or of bismuth subsalicylate 0.2 Gm., and potassium iodide by mouth. He is now clinically and serologically cured and his spinal fluid is entirely normal. At times the disease may respond quite satisfactorily; more often it will test the skill and knowledge of the physician at every turn.

#### SYPHILIS AND PREGNANCY

Moore<sup>7</sup> has made the statement that an untreated syphilitic woman has only one chance in six of bearing a living healthy child as compared with three chances in four with a healthy woman. And this ignores the further fact that in children born alive of syphilitic mothers both the mortality and the morbidity rates are much higher than among the children born of non-syphilitic mothers. However, prenatal syphilis is absolutely a preventable disease. It depends on frequent blood Wassermann tests throughout every woman's pregnancy and an immediate institution of specific therapy when the syphilis is discovered. Every pregnant woman should have a Wassermann test early in pregnancy, before the fifth month and again at the seventh or eighth month. The Cooperative Clinical Group<sup>8</sup> has found that far better results are achieved if the disease is discovered and therapy started before the fifth month of pregnancy giving preferably at least fifteen injections of arsphenamine or neoarsphenamine, and a like amount of appropriate heavy metal; e. g., bismuth salicylate. If syphilis is discovered late in the pregnancy, some treatment begun even at this time and continued up to the termination of pregnancy may be of great value in the production of a living child. If the pregnant syphilitic woman is seen early enough it may be possible to give a course of arsphenamine or neoarsphenamine or Mapharsen followed later by a course of bismuth. It is always well to terminate the therapy with an arsenical preparation because of its more potent action on the spirochetes. The woman who has had syphilis should probably be treated through every pregnancy because of danger of transmission of organisms to the fetus through the placental circulation. In isolated instances in which a patient is arsenic sensitive it would be well to give alternate courses of bismuth injections and of inunctions of Strong Mercurial Ointment up to the termination of the pregnancy, from forty to fifty rubs being considered as a course of treatment. The pregnant woman stands antisypilitic therapy very well, the incidence of arsenical reactions being lower than in her nonpregnant syphilitic sister.

#### TREATMENT OF PRENATAL SYPHILIS

The best treatment, and likewise the correct treatment, of prenatal syphilis consists in the prophylaxis of the disease through discovering the mother's difficulty early and instituting adequate, continuous therapy up to the birth of the child. However, all too often the disease is discovered late or is never recognized until the birth of the child. In a way, such syphilis may be looked on as comparable to acquired syphilis in the secondary stage. It is generalized; the patient has built up little or no immunity to the process. Moreover, the lesions are of a high degree of virulence, so that from both the infant's standpoint as well as that of the public health it is essential that the disease be put under control as early as possible. For this purpose there is no drug to compare with the arsenicals. At Western Reserve University the drug neoarsphenamine is dissolved in from 2 to 3 cc. of distilled water and deposited under the loose tissues on the side of the scalp, next to the fascia. It is given in a beginning dose of 0.005 Gm. per kilogram and worked up to a maximum of 0.01 Gm. per kilogram. There is very little local reaction and the tissues of the buttocks are conserved for heavy metal

6. Epstein, S. H.; Solomon, H. C., and Kopp, Israel: *Dementia Paralytica*, J. A. M. A. **106**:1527 (May 2) 1936.

injections. Moore prefers sulfarsphenamine in a beginning dose of 0.015 Gm., worked up to a maximum of 0.025 Gm. per kilogram. He feels that babies stand the therapy better than adults. He advises giving the injection concentrated in from 2 to 3 cc. of distilled water in the buttocks. Others are fearful of its use and employ Bismarsen N. N. R. (bismuth arsphenamine sulfonate) in a dose of 0.005 Gm. up to 0.01 Gm. per kilogram injected intramuscularly in 2 cc. of sterile distilled water. The infant may be given a course of from eight to ten such injections, followed immediately by a series of intramuscular injections of a bismuth salt; e. g., bismuth subsalicylate 2 mg. per kilogram for a total of eight injections. On the other hand, if injections are given twice a week one may employ in appropriate dose bismuth sodium tartrate, or iodobismutol. If desired, one may employ in place of the bismuth 1 Gm. of Strong Mercurial Ointment placed each day on the inner surface of the abdominal binder. The old fashioned mercury with chalk by mouth is prone to upset the stomach, though it may be tried occasionally as a course, from one-sixth to one-third grain (10 to 20 mg.), being given three times a day. The patient

#### *Mercury with Chalk*

R 100 pills, Mercury with Chalk..... 0.01 to 0.02 Gm.  
Signa: One, three times a day.

should receive at least four or five courses of the arsenical and of the alternating heavy metal. The blood Wassermann test should be taken several times a year and a lumbar puncture should be performed at the end of one year of treatment. As a rule, treatment should be kept up until the blood Wassermann and spinal fluid reactions have been negative for one year. As yet I am unwilling to recommend the indiscriminate use of acetarsone by mouth in the treatment of congenital syphilis. It is still too much in the experimental stage.

With late prenatal syphilis one is dealing with a disease to which the body has worked up a definite immunity. It is true that there are specific problems with this phase of prenatal syphilis; e. g., interstitial keratitis and syphilis of the central nervous system. Otherwise, the patient may be treated much as one with latent acquired syphilis, the arsenicals being used in dosage comparable to the weight of the individual. Potassium iodide or sodium iodide is indicated in these cases. Moreover, the treatment of late prenatal syphilis must be looked on as a possible prophylactic of more severe complications; e. g., of the central nervous system, eighth nerve deafness or interstitial keratitis.

In patients with interstitial keratitis it is essential that the diagnosis be made as early as possible and energetic alternating courses of neoarsphenamine or of arsphenamine or of Mapharsen, with bismuth be employed. For the bismuth, Moore sometimes substitutes intramuscular injections of mercuric succinimide 0.01 Gm. Potassium or sodium iodide is given in large doses from 2 to 6 Gm. a day, in old cases with scars, not in acute cases. Naturally, local therapy also is indicated. If the keratitis is seen in the early stages, it generally responds to this therapy. In older cases there may be more or less scar formation and difficulty with vision. It is well to continue the alternating arsenical and heavy metal therapy for at least two years. This may be the means of obviating relapses or of preventing possible extension to the other eye. Many times nonspecific therapy has been most helpful in the treatment of resistant keratitis; e. g., the intramuscular injection of boiled milk or the intravenous injection of

typhoid-paratyphoid vaccine. One may start with a dose of 1,000,000 and repeat in three hours, doubling the dose with each double injection and administering it every three or four days, for a series of from five to ten chills. Malaria therapy is especially valuable in old resistant keratitis, and I have seen it succeed when all other measures failed.

Involvement of the central nervous system in early or late prenatal syphilis is almost a problem to itself. The measures advised with acquired syphilis may be used. In juvenile tabes or dementia paralytica the outlook is very guarded. Even though the disease is checked there is usually little left except a vegetative animal. In other forms the response to therapy may be quite good. It is not advisable to use tryparsamide in prenatal syphilis; there is too much danger of misunderstanding and of damage to the optic nerve.

#### CONCLUSIONS

The best treatment for all forms of syphilis is prophylaxis. This can be achieved by better education of the public and of the physician, by the routine use of the Wassermann test or of similar flocculation tests in all our patients, especially in pregnancy when repeated tests should be made throughout the pregnancy. Moreover, routine Wassermann tests of all children would obviate much interstitial keratitis and eighth nerve deafness. Once syphilis has been discovered it should be thoroughly treated with arsenicals, bismuth preparations or mercury, exhibited in alternating continuous courses. The average cases of early syphilis require at least thirty injections of an arsenical and a like amount of heavy metal, and treatment should be kept up for one year after all signs and symptoms of the disease have disappeared. As explained in the text, appropriate measures must be adopted for syphilitic involvement of certain tracts or of special organs.

## Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT.  
HOWARD A. CARTER, Secretary.

### AIRNET AIR FILTER ACCEPTABLE

Manufacturer: Airtel Air Filter Company, Chicago.

The Airtel Air Filter is designed to filter the outside air, eliminating a large percentage of the pollen, dust and dirt, for the relief of symptoms of hay fever. It is especially adapted for use in any ordinary room in home, office, hotel or hospital.

The portable metal cabinet used is 24 inches wide, 12 inches high and 12 inches deep. There is a triple louver in the back to keep out rain or snow. The unit has a 9 inch circular opening in the center of the front of the cabinet through which the filtered air is discharged into the room. Its shipping weight is 75 pounds.

A motor manufactured by a well known concern and fitted with a propeller type fan is used in this unit. The motor and fan are mounted in a tube 9 inches in diameter and 6 inches deep. This tube concentrates the filtered air and forces it through the opening in the front of the cabinet.

A double filtering unit 2½ inches wide, about 12 inches high and about 24 inches wide fits in the back of the cabinet. The outside air is drawn through openings in the back of the cabinet and then through the double filtering unit. There is an air space of about 2½ inches between the two filters. This

Airtel Air Filter.

air space between filters leads to efficiency, in the opinion of the firm, because it is more difficult for pollen, dust and dirt to pass the second filter.

The Airnet Air Filter supplies approximately 300 cubic feet of air per minute and uses about the same amount of current as a 40 watt lamp. It can be attached to any electric socket, alternating or direct current.

The manufacturer submitted evidence showing that more than 95 per cent of the pollen was eliminated by means of this unit and its cellulose filter. The device was tried in an institution acceptable to the Council and the firm's submitted evidence was verified.

In view of the favorable report, the Council voted to include the Airnet Air Filter in its list of accepted devices.

## Council on Foods

THE COUNCIL ON FOODS HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT.

FRANKLIN C. BING, Secretary.

### THE NUTRITIONAL SIGNIFICANCE OF GELATIN

Experimental investigations of the nutritive value of gelatin were begun early in the nineteenth century. A considerable mass of evidence has accumulated since that time. The older experiments, including the contributions of Voit and of Murlin on the so-called protein sparing action of gelatin, have been reviewed by Lusk<sup>1</sup> and others. In recent years much attention has been directed to the amino acid makeup of gelatin. The results of laboratory work have been reflected in advertising copy and in popular articles on nutrition. As might be expected, publicity that is promulgated by biased or scientifically untrained persons has been both favorable and unfavorable and, in the opinion of the Council, frequently has been misleading. Thus it has been stated that because gelatin is biochemically classed as an incomplete protein, lacking in certain essential amino acids, it is a food that should be avoided. And the use of gelatin as a means of increasing the protein content of the diet has been recommended just as enthusiastically as its use as a food has been condemned. Since the discovery of the dramatic success that has been reported to be attendant on the prescribing of aminoacetic acid to patients with certain myopathies, the advertising of one firm in particular has called attention to the relatively high proportion of this amino acid in gelatin and has suggested the use of gelatin in the treatment of muscular dystrophies. Gelatin has been recommended also for inclusion in the diet of infants. In the present report the Council has endeavored to evaluate the nutritional claims made for this food in the light of available evidence.

**Preparation and Composition of Gelatin.**—Gelatin is a protein derived from the collagen present in white fibrous tissue. It can be obtained from tendon, cartilage, bone and skin by boiling with water. This process is usually referred to as "hydrolysis," although there is some evidence that the changes involved are physical rather than chemical. There are several methods in common use for the commercial preparation of gelatin. Cow skins and trimmings are usually steeped for several weeks in a solution of lime water, then washed and boiled with water. Pig skins and trimmings are subjected to a preliminary treatment with acid. Bones are treated to remove the fat and mineral constituents, and the organic residue is largely converted into gelatin by boiling with water. Fish skins are a minor source of gelatin; they require only treatment with water to alter the collagen. Regardless of the source, there is obtained by appropriate preliminary treatment an aqueous solution containing gelatin. This is filtered, the water is evaporated, and the dried product is broken up and ground.

Gelatin is graded chiefly according to physical characteristics such as viscosity and jelly strength. These properties depend largely on the source of the gelatin and the method of manufacture. Different lots are therefore often tested and blended to make uniform products of the desired grade.

1. Lusk, Graham: *The Elements of the Science of Nutrition*, ed. 4, Philadelphia, W. B. Saunders Company, 1928, pp. 190, 365-367.

The dried gelatin usually consists of 85 to 90 per cent pure protein. A typical analysis of gelatin is recorded in table 1. The values for a powdered gelatin dessert are also listed because many persons think that the two products are almost identical.<sup>2</sup> It may be noted that the prepared gelatin dessert powders contain only about 10 per cent gelatin. Gelatin desserts can be prepared from edible gelatin as well as from the prepared mixtures; this may be advantageous in the preparation of low carbohydrate diets because of the possibility of omitting sugar from the final product.

Edible gelatin may contain traces of heavy metals which are present in the animal tissues from which the gelatin is derived. In order to guard against contamination during the manufacturing process the federal Food and Drug Administration has established certain limits of tolerance for arsenic, lead and copper in gelatin and other foods. These tolerances have been adopted also by the Council on Foods.

**Gelatin as a Source of Protein in the Diet.**—Many investigations over a period of years have brought out the significant fact that the nutritive value of proteins is measured largely by their digestibility and their amino acid makeup. It is interesting to note the occasional statement from prejudiced sources that because gelatin is obtained by partial hydrolysis it is partly digested to begin with and therefore is easily digested when eaten. Of course gelatin is readily digested by the proteolytic enzymes of the alimentary tract; but from the practical point of view the ready digestibility of gelatin does not confer on it any superiority over the common proteins.

The most extensive analysis of gelatin for amino acids is that reported by Dakin in 1920. His figures, which were

TABLE 1.—Typical Analyses of Gelatin and Gelatin Dessert Powder

	Gelatin, per Cent	Gelatin Dessert Powder, per Cent
Moisture .....	10.0	0.8
Ash .....	1.2	0.2
Fat (ether extract) .....	0.0	0.0
Protein (N × 5.5) .....	88.5	11.0
Carbohydrates .....	0.0	86.0
Tartaric or citric acid .....	none	2.0
Added flavor .....	none	present
Added color .....	none	present
Calories per gram (approximate) .....	3.5	3.9

based largely on the isolation of the individual amino acids, are recorded in table 2, together with additional data obtained by later investigators.<sup>3</sup> It is interesting to note that the sum of the nitrogen in the form of the various amino acids, plus the ammonia nitrogen reported by Dakin, amounts to 91 per cent of the nitrogen of gelatin. From the standpoint of our present knowledge of protein composition, this means that the amino acid makeup of gelatin is well known. The figures show that a number of amino acids have not been found in gelatin or are present in very small concentration. Valine, isoleucine, hydroxyglutamic acid and tryptophane are lacking. Tyrosine, cystine and methionine are present in small amounts. According to the results obtained in the feeding experiments of Rose and his collaborators, the essential amino acid which was later identified as alpha-amino-beta-hydroxybutyric acid<sup>4</sup> (and now called threonine<sup>5</sup>) is present in much smaller amounts in gelatin than in the casein of milk.<sup>6</sup> To date the following amino acids have been shown by feeding experiments with animals to be essential for growth: leucine, isoleucine, histi-

2. The values of gelatin are from the analysis published in *THE JOURNAL* Feb. 27, 1932, p. 737, and of the powdered gelatin dessert from the analysis published May 12, 1934, page 1566.

dine, lysine, cystine or methionine,<sup>7</sup> phenylalanine, tryptophane and threonine. Future investigation may show that the animal body is incapable of synthesizing other amino acids.<sup>7a</sup> According to available data, gelatin may be classed as an incomplete protein because it lacks or contains too low a concentration of isoleucine, tryptophane and methionine.

It is the opinion of the Council that the amino acid composition of gelatin is of no practical disadvantage unless gelatin is the sole source of protein in the diet. The essential amino acids that are lacking in gelatin can and should be obtained from other sources in the diet. No one would attempt to live on a diet in which gelatin forms the sole source of protein. As a matter of fact, several investigators have attempted this feat as a scientific experiment without success. Kauffmann<sup>8</sup> reported in 1905 some feeding experiments in which he derived nitrogen entirely from gelatin supplemented with tyrosine, cystine and tryptophane and remained in nitrogen balance for a few days. His experiments, however, are inconclusive and are of historic interest only.

Gelatin, because of its swelling properties, cannot be eaten readily in the dry form or sprinkled on cereal. It is usually consumed as a solution which, if the concentration of gelatin is approximately 1 per cent or more, forms a gel on cooling. An ordinary serving of a gelatin dessert contains about 2.5 Gm. of gelatin. Recipes have been suggested in which a concentration of gelatin as high as 10 per cent may be prepared in the form of hot soups. It requires considerable ingenuity, however, to formulate a menu that contains more than about an ounce of dry gelatin per day.

Much information of lasting value has been gained through experimental studies of the nutritive advantages and disadvantages of gelatin. The report by Jackson and his collaborators<sup>9</sup> includes a review of the work to 1929 on the supplementary value of gelatin added to other proteins in the diet of rats. Thus it has been shown by Osborne and Mendel<sup>10</sup> that gelatin, which contains a relatively high concentration of lysine, will supplement gliadin, which contains about one-tenth as much of this essential amino acid. However, the application of these observations to human nutrition is obscure. The human being does not ingest synthetic diets, and an actual deficiency of lysine in the diet has never been demonstrated.

The suggested use of gelatin (containing 25 per cent of aminoacetic acid) in the treatment of the myopathies has already been mentioned. The dosage of aminoacetic acid in the treatment of myasthenia gravis or pseudohypertrophic muscular dystrophy usually is from 20 to 30 Gm. It should be apparent that gelatin can furnish only a small proportion of the proper dosage of this amino acid. In the opinion of the Council it is improper for manufacturers to exploit gelatin in connection with the observations on the use of aminoacetic acid in the treatment of the myopathies. Even if it were possible to secure appreciable quantities of aminoacetic acid by eating large quantities of gelatin, the recommendation to do so is objectionable. Each patient requires a specific amount and, in the opinion of the Council, to try to take aminoacetic acid in the form of gelatin would not only be haphazard but in many cases ineffective.

**Other Uses of Gelatin of Interest in Nutrition.**—Because of its characteristic physical properties, gelatin has a number of uses in the food industry. For example, it is customary to incorporate about 0.5 per cent of gelatin in many ice cream mixtures.<sup>11</sup> It is added in order to improve the "smooth" consistency of the product by enhancing its ability to be whipped and in other ways. Gelatin may also be an important ingredient of confections such as marshmallows.

**Effect of Gelatin on Digestibility of Milk.**—Of particular interest to physicians is the evidence regarding the effect of the addition of gelatin to milk. This has been supposed to

increase the digestibility of the milk and in the past the use of gelatin in infant feeding was looked on with favor among pediatricians. It has been thought that gelatin as a colloid would coat the newly formed casein curds in the stomach and prevent their coalescence into larger curds. Some evidence has been obtained which indicates that the curd formed when milk plus gelatin is treated with acid tends to be softer than the curd formed with milk alone plus acid.

Clinical studies of the value of gelatin in infant feeding have yielded questionable or conflicting results. Julius Hess and Chamberlain<sup>12</sup> reported an outpatient study on infants fed gelatin. The gelatin was well tolerated but there was a tendency toward the formation of foul smelling, firm stools which were grayish yellow and which at times were passed with difficulty. Other infants receiving egg yolk in place of gelatin passed stools which were more plastic and in general were canary colored. Perlman<sup>13</sup> observed a slightly higher growth rate in infants fed gelatin than in infants fed the same diet without gelatin. From the observations reported by Elterich, Boyd and Neff<sup>14</sup> as a result of a careful study of eleven infants under hospital supervision, it may be concluded that gelatin does not specifically accelerate growth but may increase the caloric intake.

The use of gelatin in the form of an isotonic solution which also contained dextrose and sodium chloride has been suggested

by Kugelmass<sup>15</sup> and by Halpern<sup>16</sup> for the prevention of weight losses in the first few days of life of new-born babies. Senn,<sup>17</sup> however, while confirming the fact that loss in weight is not so great when this solution is used, concluded that it is not a safe therapeutic procedure because it occasionally gives rise to edema formation and fails to prevent dehydration fever.

**Allowable Claims for Gelatin.**—In view of the available evidence the Council believes that gelatin properly made is a wholesome food, that it has special usefulness when one desires to add variety to the diet by incorporating gelatin in nutritious soups or pleasant desserts which appeal to the appetite of many persons, and that for these reasons gelatin is often a useful food for inclusion in the diet of healthy persons or of sick or convalescent patients. Gelatin appears to be well tolerated. The claim that gelatin is an aid in the digestion of milk, however, is in the opinion of the Council not established. The claim that gelatin is of value as a source of aminoacetic acid in the treatment of some of the myopathies cannot be recognized; in the light of present evidence, gelatin has no special significance as a source of amino acids in the diet. Indeed, it is notoriously deficient in certain essential amino acids.

## RESPIRATORY IRRITANTS: THEIR EFFECTS AND PREVENTION

Little has been written on the influence of soot on the development of tumors of the lungs. The concentration of coal smoke in most of the large cities in this country, however, is such that it is important to determine the effects of this daily contamination of the inspired air. Seelig and Benignus<sup>1</sup> have reported an experimental study dealing with the carcinogenic power of soot on the lungs. They endeavored to determine whether or not the soot deposited out of coal smoke played a part in the development of tumors of the lung in white mice. The soot used in the experiments was secured by sweeping the flue of a hospital furnace that burned Kentucky bituminous nut coal, and it was substituted for sawdust and shavings as a bedding material for the mice. Dust from the soot was raised by the normal activity of the mice, but in addition each cage was violently shaken two or three times a day. The principal constituents of the soot were silica, tarry matter, sulfur and volatile salts, including ammonia. One hundred mice were subjected to this atmosphere of soot dust, and fifty controls were kept under normal laboratory conditions at a distance from the cages containing the experimental animals. The animals of both groups were about 3 months old. As each mouse died, a necropsy was performed, except on the thorax, after which the mouse was placed in 10 per cent solution of formaldehyde with the lungs in situ. After three or four days the lungs were removed, embedded in paraffin and sectioned serially. At the end of six months, 20 per cent of both groups had died. At the end of a year, about 60 per cent of the animals in both groups had died, and at the end of eighteen months all the animals had succumbed. The histologic study showed that in the control group of fifty mice there was only one with adenocarcinoma of the lung, an incidence of 2 per cent. In contrast to this, eight mice in the experimental group

showed adenocarcinoma of the lung, an incidence of 8 per cent. In two additional mice there were tumors resembling bronchiogenic carcinomas, but these were eliminated since they could not be differentiated from active nonmalignant intrabronchial hyperplasia.

Since the mice subjected to soot dust showed an incidence of lung cancer four times as great as the control group, the next question was What is the comparative incidence of human cancer of the lung in urban and rural communities? The available data were tabulated for the authors by Dr. Halbert L. Dunn of the United States Bureau of the Census. Although a consistent and markedly higher death rate in the cities is noted in these tables, too many factors enter into an interpretation of the census figures to permit dogmatic conclusions. These figures provide sufficient evidence, however, to show the necessity for further studies of the subject.

Coal dust is not the only irritative constituent of the air that may be a menace to the public health. Some problems of respiratory protection in the petroleum industry have been discussed by Kintz and Fowler<sup>2</sup> of the U. S. Bureau of Mines. An atmosphere is dangerous when it contains one or more foreign substances, such as gas, dust, mist or fumes, in sufficient quantity to be harmful or explosive, or when it does not contain enough oxygen to allow working with maximum efficiency or to support life, or when the temperature and humidity are too high for human endurance. Satisfactory solution of problems created by atmospheric conditions that are unsafe or detrimental to the health and efficiency of workers can be reached, these writers say, only after careful analysis of individual circumstances. The specific impurity in the air to which each worker on each job is exposed must be determined, its dangers recognized, and effective protective measures taken—measures that not only protect but offer a minimum of inconvenience to the worker.

Some methods for determining the relative harmlessness of atmospheric conditions are available. Detectors for inflammable gas, toxic gas, pyrotannic acid, carbon monoxide and hydrogen sulfide are available. Deficiency in the oxygen content of the air can also be determined. Instruments are available for counting and recording the amount of dust in the air. The most satisfactory procedure when possible is to render the inspired air harmless. Under some circumstances this does not seem to be always possible. When it is necessary for individuals to live under dangerous atmospheric conditions, the oxygen supply and the nature and degree of harmfulness of the toxic substances in the air should be known as accurately as possible. Such protective equipment as the canister-type gas mask, dust respi-

rators, self-contained oxygen breathing apparatus, hose masks and air-line respirators may serve a limited purpose.

Intense interest has been stimulated in certain quarters in the problems of respiratory irritants, and factual data are rapidly accumulating. The interest also of those not technically employed in this field should be stimulated toward the public health problems involved.

#### LOSS OF CEVITAMIC ACID

Once the constitution and chemical nature of vitamin C (cevitamic acid) were established, it became possible to develop strictly chemical methods for determining this dietary essential in food materials, tissues and body fluids. The most widely used method employs the readily reduced organic compound 2,6 dichlorophenol indophenol as an indicator; the specificity of the reaction as well as the comparison of the results so obtained with the time-consuming bio-assay on guinea-pigs has received careful attention. The wide usefulness of the titration method has been demonstrated. Thus, not only is it possible to note changes in the vitamin C content of foods as a result of processing—cooking, pasteurization, storage—but the localization of cevitamic acid in certain animal tissues and the variations in its concentration in blood and urine can be determined in a relatively short time.

That the content of this dietary essential in the plasma parallels its content in the urine has been indicated by Greenberg, Rinehart and Phatak.<sup>1</sup> The average value for plasma vitamin C in twenty-five normal human subjects excreting more than 50 mg. in the urine was 0.92 mg. per hundred cubic centimeters, whereas thirteen subjects excreting less than 50 mg. had 0.44 mg. per hundred cubic centimeters in the plasma. The responsiveness of plasma concentration to intake is shown by the appreciable rises (from 15 to 69 per cent) in plasma level within two to four hours after the ingestion of 6 ounces of orange juice. The thirty-eight normal subjects were further classified into groups according to the approximate antiscorbutic value of their diet. The cevitamic acid content in the plasma of the eleven subjects rated as low was found to be 0.55 mg. per hundred cubic centimeters; of the nineteen rated as fair, 0.75 mg., and of the eight rated as good, 1.10 mg.

These studies show the wide variation in the vitamin C content of the blood of so-called normal individuals and the close correlation with the amount ingested. That the foregoing relationships merit attention in the clinic is emphasized by the recent observations of Daniels and Everson<sup>2</sup> that ingestion of

acetylsalicylic acid is followed by a pronounced increase in cevitamic acid in the urine. Thus, on a constant dietary regimen, four children given  $2\frac{1}{2}$  grains (0.16 Gm.) of the drug showed from 100 to more than 200 per cent increase in the loss of vitamin C in the urine. It is obvious that, in certain cases in which prolonged administration of acetylsalicylic acid is required, particular attention must be given to the allowance of vitamin C lest scurvy appear. Doubtless other similar antagonisms exist. As the human requirement for most of the recognized indispensable accessory food substances is not known, it follows that, so far as possible, optimal nutrition should be maintained in treating the patient.

#### EXTRASYSTOLES

Extrasystoles, the most common cause of irregularity of the heart's action, were formerly regarded as a symptom of myocardial damage. A valuable part of Sir James Mackenzie's great work was the clinical differentiation between extrasystoles and auricular fibrillation; at the same time he showed the relative unimportance of the former and the importance of the latter. However, to deny any significance to extrasystoles would be to lose a sign which might help in diagnosis and treatment. According to Boas and Levy,<sup>1</sup> at least 50 per cent of patients with extrasystoles have normal hearts as far as can be determined. They occur in a large proportion of elderly men and not infrequently in young subjects. Mackenzie<sup>2</sup> noted premature beats in a man at the age of 69 in whom they were first discovered at the age of 18. This patient had earned a living at work that entailed great bodily strain and yet he was in fairly good health after fifty-one years with premature beats. Grassmann<sup>3</sup> reported a case in which they were known to be present for sixty-seven years. Extrasystoles are said to arise from an irritable focus in the musculature of the auricles or of the ventricles or from the auriculoventricular node. It is sometimes possible to differentiate clinically between the sites of origin. When extrasystoles originate in the auricle, the normal rhythm from the sino-auricular node is generally disturbed and there is no compensatory pause. When extrasystoles originate in the auriculoventricular node or in the ventricle, the sino-auricular rhythm is maintained. There is then a compensatory pause after the premature beat, and the intervals before and after it are together equal to two normal beats. When the extrasystole is ventricular, the auricular wave (P) in the electrocardiogram is unaffected in shape and position but may or may not be visible, owing to its inclusion in the ventricular complex (QRST).

1. Boas, E. P., and Levy, Hyman: Extrasystoles of Clinical Significance, *Am. Heart J.* 11: 264 (March) 1936.

2. Mackenzie, James: Diseases of the Heart, London, Oxford University Press, 1913.

3. Grassmann, Karl: Zur prognostischen Wertigkeit und Behandlung der praktisch-wichtigsten Herzrhythmen, München, med. Wchnschr. 67: 5 (Jan. 2) 1920.

1. Greenberg, L. D.; Rinehart, J. F., and Phatak, N. M.: *Proc. Soc. Exper. Biol. & Med.* 35: 135 (Oct.) 1936.

2. Daniels, Amy L., and Everson, G. I.: *Proc. Soc. Exper. Biol. & Med.* 35: 20 (Oct.) 1936.

The causes of extrasystoles are not always clear. There is slight support for the theory that they are more likely to arise in the cardiac area, where there is the greatest strain. Campbell<sup>4</sup> reported their presence in about 20 per cent of 500 consecutive cases in the cardiographic department at Guy's Hospital. About one fourth of these patients apparently had no heart disease whatever; another one fourth had rheumatic heart disease; pregnancy seemed to be the exciting cause in some cases. High blood pressure (over 170) accounted for 16 per cent, and myocardial or atheromatous changes for 18 per cent. A few cases were associated with exophthalmic goiter, with syphilitic arterial disease and with the administration of quinidine. Extrasystoles may be induced by smoking or by coffee, or by the administration of digitalis or the salicylates; such extrasystoles disappear when the offending agent is removed. Acute infections can be the immediate cause of extrasystoles. When they appear suddenly in the course of an acute infection it is an indication that the heart has been injured by the infectious process. Extrasystoles that arise in the auricles in patients with mitral stenosis are said to presage the appearance of auricular fibrillation. They may be closely linked with progressive disease of the coronary arteries, especially when they appear for the first time in middle age or later. Boas and Levy<sup>1</sup> observed a significant relationship between the occurrence of extrasystoles and of anginal attacks. In the records of 974 patients with coronary sclerosis, fifty-three had extrasystoles. Twenty-one per cent of these fifty-three patients had died, whereas only 10.4 per cent of the 921 patients with coronary disease without extrasystoles had died.

Extrasystoles are encountered less frequently as the heart rate becomes more rapid. They are exceedingly rare at heart rates of 120. For this reason they are unusual in febrile diseases and in hyperthyroidism. Physical exercise usually abolishes extrasystoles simply by accelerating the heart rate. Boas and Levy analyzed 183 cases in private practice that presented extrasystoles. In two thirds of these cases the heart rate was between 70 and 100. Ventricular extrasystoles did not occur in patients whose hearts were normal at heart rates above 110, and in only two instances (both children) did auricular extrasystoles occur at these rates. The great majority of their patients who had extrasystoles during rapid heart rates had definite myocardial disease. Extrasystoles were not present in patients with hyperthyroidism except in the presence of complicating heart disease and multifocal extrasystoles. In persons whose hearts are otherwise normal, extrasystoles do not portend present or future heart disease, and their appearance in frank heart disease usually does not add to the gravity of the prognosis.

4. Campbell, Maurice: The Etiology and Significance of Extrasystoles, *Guy's Hosp. Rep.* 79: 142-158 (April) 1929.

## Current Comment

### PAINTING THE ORANGE

Today the orange is universally recognized as a rich source of vitamin C and therefore a desirable fruit for children. The natural color and other characteristics of the rind vary with different varieties and with the season. Once these features served to some extent as marks of identification. This is not true today, when there is current a tendency to "improve on nature." The inherent color of the rind of certain varieties of the orange is not an index of maturity of the fruit or of the degree of sweetness of the juice. Green pigment persists in the skin of mature fruit of high quality. Many growers apparently believe that the presence of chlorophyll in the pericarp impairs the marketability of the fruit. Several years ago the practice of exposing oranges to ethylene gas for from two to four days was introduced. The ethylene causes a blanching of the green color and a consequent unmasking of the yellow pigments also present in the skin. The United States Department of Agriculture has ruled that this process does not in itself constitute adulteration, and there is evidence that the nutritional value of the juice is not affected by it. More recently a rapid method of coloring has been employed. The fruit is dipped in a solution of a harmless coal tar dye, which gives to the resulting "painted oranges" a more uniform, brilliant color. Food laws require that the presence of dyes must be declared by having the phrase "color added" stamped on each orange. The staining of unripe or damaged fruit by any method in simulation of oranges of greater maturity or of superior quality constitutes adulteration under the Food and Drugs Act. The degree of maturity of the orange is determined by chemical analysis of the amount of sugar and citric acid in the juice. Unless there are eight parts of sugar to each part of acid, the fruit is held to be unripe and inferior. The state of Florida has recently provided rigid regulation of the packaging and marketing of citrus fruit according to more exacting standards than those required by the federal government. The United States Department of Agriculture accordingly has agreed to wait until September 1937 before action will be taken. Thereafter interstate shipments of inferior oranges that have been colored will be liable to seizure and destruction. The Florida regulations in large measure should serve to remove the necessity for federal action. Accurate information concerning the effect of the artificial coloring of oranges on the consumption of the fruit is not available. The phrase "color added" stamped on each stained orange has certainly puzzled alert housewives, many of whom under the direction of their family physician are buying oranges for the baby. Consumers have questioned whether the colored oranges are of high quality. They have tasted the juice warily and have inquired whether the vitamin content is as high as in the uncolored fruit. Some consumers have expressed the opinion that colored oranges do not keep as well as the untreated russet colored fruit. Others have asked whether the "painted" rind is suitable for

making marmalade and candied orange peel. These questions are evidence of intelligent interest on the part of the public. The promulgators of the coloring of oranges should arrange to answer them decisively by scientific evidence.

### RADIO BROADCASTS

The American Medical Association and the National Broadcasting Company are presenting the second series of dramatized health broadcasts under the title *Your Health*. The first broadcast in the new series, the thirty-second dramatized cooperative broadcast under the title *Your Health*, was given October 13. The theme for 1936-1937 differs slightly from the topic in the first series, which was "medical emergencies and how they are met." The new series is built around the central idea that "100,000 American physicians in great cities and tiny villages, who are members of the American Medical Association and of county and state medical societies, stand ready, day and night, to serve American people in sickness and in health."

The program will go out on the Blue network instead of on the Red network, as originally announced.

The topics are announced monthly in advance in *Hygeia*, the Health Magazine, and three weeks in advance in each issue of *THE JOURNAL*. The topics and speakers for the next three programs are:

December 29. Health Assets and Liabilities. W. W. Bauer, M.D.  
January 5. "Smog." W. W. Bauer, M.D.  
January 12. Winter Health Hazards. W. W. Bauer, M.D.

The time of the broadcast is Tuesday afternoon at 4 o'clock central standard time (5 o'clock eastern time, 3 o'clock mountain time, 2 o'clock Pacific time).

### ARKANSAS

**Annual Reregistration Due January 1.**—Every licentiate of the Arkansas Eclectic Medical Examining Board must register annually with the secretary of the board between January 1 and the last day in February and pay a fee, if a resident of Arkansas, of \$2 and, if a nonresident, of \$4. The failure of a licentiate to pay the required fee by March 1 automatically suspends his right to practice while delinquent. If he fails for three successive years to pay the required fee, his license is to be cancelled, and thereafter he will be reinstated only on such a showing to the board of moral character and professional qualifications as would entitle the applicant to the issuance of an original license and the payment of the same fees as are required for the issuance of an original license.

### CALIFORNIA

**Plague Infection.**—According to *Public Health Reports*, plague infection has been proved, by animal inoculation, in fleas taken from twenty-four ground squirrels, *Citellus beecheyi* fisheri, shot October 10, in Holcomb Valley, six miles north of Pine Knot, in San Bernardino County.

**Annual Registration Due January 1.**—Every practitioner of medicine and surgery holding a license to practice in California is required by law to register annually, on or before January 1, with the secretary-treasurer of the board of medical examiners, and at that time to pay a fee of \$2. Failure to pay the required fee within sixty days after January 1 works a revocation of a license and thereafter a license may be reissued only after application and the payment of a \$10 penalty.

**Society News.**—Dr. David G. Ghrist, Glendale, addressed the San Diego County Medical Society, December 8, on "Differential Diagnosis and Treatment of Chronic Arthritis."

At a meeting of the San Diego Academy of Medicine, December 3, Dr. John H. Musser, New Orleans, was the guest speaker.—At a meeting of the staff of Peralta Hospital, Oakland, Drs. John W. Sherrick and Emery R. Ranker discussed chorio-epithelioma of an ovarian pregnancy and of the testis respectively, among other speakers.

**Fifty-Fifth Series of Popular Lectures.**—Stanford University School of Medicine, San Francisco, announces the fifty-fifth series of popular medical lectures to be given in Lane Hall on alternate Friday evenings during the winter quarter. Following is the schedule:

Dr. Jacques P. Gray, San Francisco, January 8, Syphilis and Its Control.  
Dr. Benjamin W. Black, Oakland, January 22, The County Hospital and the Public.  
Dr. William C. Voorsanger, San Francisco, February 5, Recent Advances in the Treatment of Tuberculosis.  
Dr. Frederic C. Bost, San Francisco, February 19, The Crippled Child.  
Sanford M. Moose, D.D.S., San Francisco, March 5, Behind the Scenes of Pain Relievers in Dentistry.  
Dr. Jay Marion Read, San Francisco, March 19, The Rising Death Rate from Heart Diseases.

### COLORADO

**New Tuberculosis Research Laboratory.**—A tuberculosis research laboratory has been established in Colorado Springs, to be operated by the Colorado Research Foundation assisted by scientists of the Colorado College. The laboratory was financed by the city of Colorado Springs and the PWA. It contains 3,000 square feet of floor space divided into twelve rooms including a monkey room, guinea-pig and rabbit quarters, five individual laboratories, x-ray room, spectrographic room, photographic dark room, director's office and sterilizing room.

### CONNECTICUT

**Annual Registration Due During January.**—Every practitioner of medicine and surgery holding a license to practice in Connecticut is required by law to register with the state department of health during January and at that time to pay a fee of \$2. Licentiates who have retired from active practice or who live out of the state must register annually but need not pay a fee. A practitioner failing to register is liable to a fine of not more than \$5.

**Outbreak of Food Poisoning.**—Eighteen orderlies and one ward maid at New Haven Hospital, New Haven, were attacked October 26 with diarrhea and abdominal cramps. The illness was self limited and all were clinically well within forty-eight hours. The etiologic factor was not established. Duplicate stool specimens from each patient failed to show any recognized pathogen. The source of the outbreak was not established, although it was assumed to be of food origin because of the simultaneous outbreak, and all those involved received their meals from one source. The personnel of the serving kitchen was also studied bacteriologically, but no pathogens were isolated. No subsequent cases developed.

### DISTRICT OF COLUMBIA

**Society News.**—Dr. Garnet W. Ault addressed the Medical Society of the District of Columbia, December 16, on "Recent Advances in Proctology," and Frederick A. Fenning, counsel for the society, discussed "Court of Appeals Decisions, with Excerpts of the Evidence, in Cases Brought By and Against Washington Physicians." Dr. Samuel A. Levine, Boston, discussed "Pitfalls in the Diagnosis of Heart Disease" before the society, December 9, meeting jointly with the Washington Heart Association.—At a meeting of the Washington Ophthalmological Society, November 2, Drs. Alfred Bielschowsky, Hanover, N. H., spoke on "Etiology of Squint"; John W. Burke, "Papilloma of Canaliculus," and Leroy W. Hyde, "Hemangioma of the Orbit."

**Study of Man and Environment.**—The Academy of Medicine of Washington is planning an extended study of the medical aspects of the interaction between man and his environment. At a meeting, December 8, "The Reaction of the Individual to His Social Environment, with Special Reference to Emotions as a Factor in Disease" was presented by the committee in charge of this phase of the subject: Drs. Walter L. Treadway, assistant surgeon general in charge of mental hygiene, and Henry H. Hazen, both of the U. S. Public Health Service; Lewis C. Ecker, associate professor of medicine, Georgetown University Medical School; Earl B. McKinley, dean, George Washington University School of Medicine, and also from George Washington, Drs. Walter A. Bloedorn, professor of medicine, William J. Mallory, professor of medicine, and Vincent Du Vigneaud, Ph.D., professor of biochemistry.

## GEORGIA

**Society News.**—Dr. Stacy C. Howell, Atlanta, among others, presented a paper before the Fulton County Medical Society in Atlanta, December 3, entitled "Action of Epinephrine on the Diseased Human Eye." Drs. F. Phinizy Calhoun and Thomas F. Sellers addressed the society on "The Intra-Ocular Invasion by the Larva of the Ascaris" November 19. The speakers November 5 were Drs. Amey Chappell and Frank Lee Bivings, among others, on "Blood Studies on Negro Women During Pregnancy."

## ILLINOIS

**In Memory of Dr. Rice.**—A bronze plaque in the lobby of the Kane County Spring Brook Sanatorium, Aurora, was dedicated, December 6, to the memory of the late Dr. Imas P. Rice, superintendent, who died April 23. Dr. Rice, the first superintendent of the hospital, had held the position since March 10, 1921.

**Society News.**—Dr. Clark W. Finnerud, Chicago, addressed the DuPage County Medical Society in Naperville, November 18, on "Diagnosis and Treatment of Common Skin Diseases."—At a meeting of the Winnebago County Medical Society in Rockford, December 18, Dr. Edward L. Cornell, Chicago, spoke on "Newer Developments in Obstetrics."

**Fifty Years in Practice.**—The Adams County Medical Society held a special meeting and dinner, November 24, to honor Drs. Melinda C. K. Germann and J. W. Edward Bitter, who have completed fifty years in the practice of medicine in Quincy. Dr. J. Carl Steiner was toastmaster. Gold wrist watches were presented to both physicians. Speakers included Drs. Francis L. Reder, St. Louis, and Henry J. Jurgens, and three physicians who also have completed fifty years of practice: Drs. Levin H. A. Nickerson, Edmund B. Montgomery and William W. Williams. Dr. Germann graduated from the Quincy College of Medicine in 1886 and has been active in the civic life of the community. Dr. Bitter also graduated from the Quincy College of Medicine; he served two terms as president of the Adams County Medical Society in 1929 and 1933 and as secretary from 1922 to 1923.

## Chicago

**Rush Abolishes Fifth Year Requirement for Degree.**—The faculty of Rush Medical College recently voted to abolish the requirement of the fifth year for the degree of doctor of medicine, effective December 15. Certain additional provisions were made for students who have received the four year certificate since 1934 and who never received their degree because of illness and for students who received the certificate in the past year who were either not under contract to a hospital or whose contract could be altered by the hospital concerned to permit them to receive their degree before completing their internships.

**Society News.**—Dr. Maurice F. Lautman, Hot Springs National Park, Ark., addressed the Chicago Medical Society, December 16, on "The Present Status of the Treatment of Arthritis," and Dr. Laurence H. Mayers, "Arthritis."—At a meeting of the Chicago Pathological Society, December 14, Dr. Edward L. Compere, among others, spoke on "Pathology of the Spine."—The Chicago Pediatric Society was addressed, December 15, among others, by John Hays Bailey, Ph.D., on "Observations on the Epidemiology of Certain Streptococcal Diseases."—At a meeting of the Chicago Society of Internal Medicine, December 15, the speakers included Dr. Walter J. R. Camp on "Influence of Epinephrine on the Distribution of Potassium in the Body."

## INDIANA

**Dr. Ferree Named Chief of Health Administration.**—Dr. John W. Ferree, Bluffton, has been appointed chief of the newly created bureau of local health administration, Indiana State Division of Public Health, according to the state medical journal. Dr. Ferree, who graduated from the Indiana University School of Medicine, Indianapolis, in 1932, will supervise local health activities, help organize local departments and aid with the preparation of programs and budgets.

**Society News.**—Dr. Ernest R. Carlo, Fort Wayne, was chosen president of the Indiana Pediatric Society at its annual meeting in Fort Wayne, November 6-7. Dr. Harold D. Lynch, Evansville, was named vice president and Dr. Matthew Winters, Indianapolis, reelected secretary-treasurer.—Dr. David I. Schwartz addressed the Fort Wayne Medical Society, December 15, on "Treatment of Acute Hematogenous Osteo-

myelitis," and Dr. A. Jerome Sparks, December 1, "Management of Urinary Calculi."—Dr. Juan Rodriguez conducted an x-ray seminar before the Academy of Medicine and Surgery, Fort Wayne, December 8.—The St. Joseph County Medical Society was addressed at its fifty-first annual meeting in Mishawaka, November 18, among others, by Drs. Norman R. Kretzschmar, Ann Arbor, Mich., on "Antepartum Bleeding"; John deJ. Pemberton, Rochester, Minn., "Surgery of the Thyroid Gland," and Irving S. Cutter, Chicago, "Fight Against Puerperal Fever."—Dr. Willis D. Gatch, Indianapolis, discussed "Indications for Surgery in the Acute Abdomen" before the Carroll County Medical Society in Camden in November.—At a meeting of the Fayette-Franklin County Medical Society in Connersville, November 10, Dr. Gordon W. Batman, Indianapolis, spoke on "Early Diagnosis and Treatment of Congenital Deformities."—Dr. Byron G. Shaffer, Toledo, Ohio, addressed the Northeastern Indiana Academy of Medicine in Kendallville, November 19, on "The Surgical Aspect of Peptic Ulcer."

## KANSAS

**Society News.**—At a meeting of the Rush-Ness County Medical Society in Ransom, October 1, Dr. Clyde D. Blake, Hays, discussed "Empyema and Its Management" and Dr. Lester A. Latimer, Alexander, "Conjunctivitis, Its Management and Treatment."—The Tri-County Medical Society was addressed in Wellington, October 14, among others, by Drs. Andrew B. Rivers, Rochester, Minn., on "Treatment of Peptic Ulcer" and "The Chronic Dyspeptic"; Ferdinand C. Helwig, Kansas City, Mo., "Pitfalls in Diagnosis and Treatment in Malignant Disease," and Nathaniel G. Alcock, Iowa City, the enlarged prostate.—Dr. Leroy A. Calkins, Kansas City, Mo., discussed "Menopause Menorrhagia" before the Sedgwick County Medical Society in Wichita, December 1. Dr. Olin West, Secretary and General Manager, American Medical Association, addressed a joint meeting of the society and its woman's auxiliary, December 15.

## MASSACHUSETTS

**Mental Hygiene Officers.**—At the annual meeting of the Massachusetts Society for Mental Hygiene in Boston, November 24, Dr. Donald Gregg, Wellesley, was elected president; Walter F. Dearborn, Ph.D., Cambridge, vice president, and Dr. Charles E. Thompson, Gardner, secretary.

**Anesthetists Oppose Hospital Prepayment Plan.**—At a special meeting, November 6, the Boston Society of Anesthetists passed a resolution opposing a proposed hospital prepayment plan as it is now drawn up for consideration by Boston hospitals. The resolution declared that the present contract would tend to reduce anesthetists toward the position of technicians, place them under the control of the hospitals and set them apart from other branches of medicine. It further declared that the progress of anesthesia would be impaired and that poorer service to the patient would ultimately be the result. The resolution was passed after a series of conferences with anesthetists from New York, Rochester, Washington and other places held during the Congress of Anesthetists in Philadelphia during October.

## MICHIGAN

**Medical Director of Psychopathic Hospital.**—Dr. Raymond W. Waggoner, associate professor of neurology, University of Michigan School of Medicine, Ann Arbor, has been appointed medical director of the state psychopathic hospital to succeed the late Dr. Albert M. Barrett, who held the position for thirty years. Dr. Waggoner, who is 35 years of age, is an alumnus of the university medical school.

**Society News.**—Dr. Robert S. Breakey, Lansing, addressed the Shiawassee County Medical Society, October 15, on renal calculi.—Samuel Lewis, D.D.S., addressed the Detroit Pediatric Society, December 2, on "Indications and Contraindications for Orthodontic Treatment in Children."—Dr. Edward Cathcart, Detroit, addressed the Oakland County Medical Society in Pontiac, November 17, on "The Association of Renal Neoplasms with Calculi."—At a joint meeting of the Muskegon and Kent county medical societies in Grand Rapids, November 18, Dr. Russell M. Wilder, Rochester, Minn., spoke on "Clinical Investigation of the Action of Protamine Insulin."—Ernest O. Melby, Ph.D., dean, school of education, Northwestern University, Evanston, Ill., discussed "Recent Trends in Education" before the Calhoun County Medical Society in Battle Creek, December 1.—Dr. Harold G. Pudleiner, Battle Creek, addressed the Saginaw County Medical Society, November 17, on hydronephrosis.

## MINNESOTA

**Annual Registration Due During January.**—Every practitioner of medicine and surgery holding a license to practice in Minnesota is required by law to register annually during January; with the secretary of the board of medical examiners, and at that time to pay a fee of \$2. A licentiate who practices without renewing his license is guilty of a misdemeanor and is liable to prosecution.

**The Bell Lecture.**—Dr. Harry E. Kleinschmidt, director of health education service, National Tuberculosis Association, New York, delivered the third annual J. W. Bell Lecture of the Hennepin County Medical Society, December 7. His subject was "The Doctor and Tuberculosis of the Future." The lectureship was established as a memorial to the late Dr. John W. Bell and each year serves as a tribute to him and to one other outstanding physician. This year the lecture commemorated Dr. Frederick A. Erb, who died October 25 while president of the Hennepin County Tuberculosis Association.

**Society News.**—Dr. Martin Nordland, Minneapolis, discussed surgical lesions of the neck before the Kandiyohi-Swift-Meeker Medical Society at Willmar, October 27.—At a meeting of the Rice County Medical Society in Faribault, October 1, Dr. Alfred W. Adson, Rochester, spoke on "Diagnosis and Surgical Treatment of Spinal Cord Tumors."—At a meeting of the Upper Mississippi Medical Society in Bemidji, October 31, among others, Dr. Oscar E. Locken, Crookston, read a paper entitled "Will the Government or the Patient Pay?" and Dr. L. Strausman, Rochester, "State Medicine as Seen in Germany."—Dr. David E. McBroom, Cambridge, was chosen president of the Minnesota Medical Officers' Association at its annual meeting, October 5; Dr. Ethel R. Beede, Faribault, vice president, and Dr. Herman E. Hilleboe, St. Paul, secretary; Dr. Arthur R. T. Wylie, Faribault, discussed feeblemindedness.

**Delegates Reaffirm Free Choice of Physician.**—Following a special meeting of the house of delegates of the Minnesota State Medical Association, November 1, the committee on public policy and legislation issued a statement to the interim committee on social security legislation of the Minnesota state legislature defining the position of the association on the medical aspects of relief. The statement reaffirmed the association's belief in the principle of free choice of physician by the recipient of relief or his guardian and preservation of the traditional physician-patient relationship. "We also believe," the statement said, "that where local private hospital facilities are available, adequate and practicable, the recipient of relief or his guardian should have the choice of hospital." Strong opposition was expressed to the practice of "bidding" for the rendering of medical services. This kind of service is not conducive to the best interests of the patient, the taxpayer or the medical profession, and free choice of physician with a reasonable allowance to the physician for his services will eliminate it, the delegates believe. The statement expressed the association's opinion that each case should be considered on its merits. It was the opinion of the spokesmen that the allowance for medical services to recipients of relief should be paid directly to the physician. They assured the interim committee that the association as a body is willing to administer to those who are unable to provide medical attention for themselves and that it wishes to cooperate with the legislature in the future as in the past. It is willing to continue the plan of medical advisory committees selected by the county medical societies to assist local relief authorities in medical matters, believing that this plan has functioned satisfactorily. The statement also recorded approval of the present forms of authorization for medical service.

## MISSOURI

**Memorial Meeting.**—The Jackson County Medical Society, Kansas City, held a memorial meeting in honor of the late Dr. Emsley T. Johnson, December 8. Dr. Johnson was the president-elect of the society. He died suddenly of a cerebral hemorrhage, November 20.

**State Prison Quarantined for Smallpox.**—Newspapers reported November 27 that the Missouri state prison at Jefferson City had been under quarantine since October 15 on account of an outbreak of smallpox. Up to November 27 seven cases had been reported. There are about 4,800 inmates in the prison.

**Society News.**—The St. Louis Medical Society was addressed, December 9, by Drs. Cyril M. MacBryde on "Insulin Response as an Index to the Dietary Management of Diabetes"; Duff S. Allen, "Effect of Goiter and Thyroidectomy in the Aged," and August A. Werner, "Relationship of Thyrotropic Hormone to Exophthalmic and Toxic Adenomatous

Goiter."—Dr. Richard L. Sutton Jr., Kansas City, addressed the Jasper County Medical Society at Joplin, November 17, on "Common Diseases of the Skin."—At a meeting of the Kansas City Dental Society, December 14, Dr. Russell L. Haden, Cleveland, presented "Reflections on the Focal Infection Problem."—Dr. Austin A. Hayden, Chicago, secretary, Board of Trustees, showed a motion picture film of the activities of the American Medical Association before the Jackson County Medical Society, December 15.—Dr. Ulysses S. Short discussed "Allergy and Its Nasal Manifestations" at a joint meeting of the St. Louis County Medical Society and its woman's auxiliary, November 24.

## NEW YORK

**Hospital Insurance for Western New York.**—The Hospital Service Corporation of Western New York will go into operation Jan. 1, 1937, with headquarters in Buffalo. Carl M. Metzger is the executive director. The plan, which offers twenty-one days of hospital care, exclusive of physicians' fees, has been approved by the Medical Society of the County of Erie. The charter provides for service for Erie, Niagara and Chautauqua counties. Eight hospitals in Buffalo, one in Lackawanna and two in Niagara Falls are participating, each represented on the board of directors. The medical societies concerned are also represented on the board.

## New York City

**Birth Control Conference.**—A Conference on Contraceptive Research and Clinical Practice will be held at the Hotel Roosevelt December 29-30 under the auspices of the Birth Control Clinical Research Bureau. Tuesday's program will be devoted to "Present Day Research in Conception" and Wednesday's to "Clinical Practice." Tuesday evening there will be a dinner meeting at which Dr. Ira S. Wile will be toastmaster and the speakers will be Drs. Hannah M. Stone; Milton C. Winternitz, New Haven; Mrs. Margaret Sanger, and Morris L. Ernst. The subject to be discussed is "Public Health and Birth Control Laws."

**Personal.**—A portrait of Mary Swartz Rose, Ph.D., professor of nutrition, Teachers College, Columbia University, was recently presented to the college by former students and associates. Dr. Rose is a member of the Council on Foods of the American Medical Association.—Dr. Thomas H. Russell has succeeded Dr. Charles Gordon Heyd, President of the American Medical Association, as executive officer of the department of surgery at New York Post-Graduate Medical School and director of the surgical service at New York Post-Graduate Hospital and Dispensary. Dr. Russell was also promoted to the rank of professor of surgery. Dr. Heyd retains his title of professor of clinical surgery.—Dr. Fred H. Albee presented a paper on "Arthroplasty of the Knee" at the meeting of the International Society of Orthopedic Surgery and Traumatology in Bologna and Rome recently and was elected vice president of the organization.—Dr. William Bierman, assistant clinical professor of therapeutics at New York University College of Medicine, was recently appointed administrative consultant in physical therapy to the department of hospitals.

**Society News.**—Dr. Morris Fishbein, Chicago, editor of THE JOURNAL, among others, addressed the Medical Society of the County of Kings, December 15, on "New Forms of Medical Practice."—Drs. Frederick T. Lord, Boston, and Frederic Maurice McPhedran, Philadelphia, addressed the Brooklyn Thoracic Society, December 18, on "Diagnosis of Pulmonary Tuberculosis" and "Pathology of Tuberculosis in Relation to Its Clinical Course" respectively.—Dr. Walter Schiller, Vienna, Austria, addressed the New York Pathological Society, December 17, on "Mesonephroma Ovarii."—The eighth clinical session on pulmonary diseases under the auspices of the Tuberculosis Sanatorium Conference of Metropolitan New York was held at Cornell University Medical College, December 2.—A section on medical history was recently organized in the Medical Society of the County of Kings and held its first meeting November 13, with Dr. Thomas Darlington as the speaker on "Medical Practice in Arizona in the Late Eighties."—Dr. Joseph Wrana gave an afternoon lecture before the Medical Society of the County of Queens, November 6, on "Common Diseases of the Cervix," and Dr. Moses Cohen spoke, November 20, on "Complications During Pregnancy and Their Management."

## NORTH DAKOTA

**Society News.**—The Rolette County Medical Society was recently organized at a meeting in Rolla, with Dr. Joseph O. Hayhurst, Rolette, as president; Dr. Bernard D. Verret, Rolla, vice president, and Dr. Milton Greengard, Rolla, secretary.—

The fall meeting of the North Dakota Academy of Ophthalmology and Otolaryngology was held at Fargo, October 31; the speakers were Dr. Trygve Oftedal, Fargo, on "Tuberculin in Ophthalmology"; Clarence Wulling, Minneapolis, "Practical Optics," and Dr. George C. Foster, Fargo, "Osteomyelitis of the Facial Bones and Skull."

### OHIO

**Bacteriologists Organize.**—An Association of Bacteriologists in Ohio was organized at a meeting in Columbus December 5, with the following officers: Dr. Noel Paul Hudson, professor of bacteriology, Ohio State University College of Medicine, Columbus, chairman; Dr. Merlin L. Cooper, assistant professor of pediatrics, University of Cincinnati College of Medicine, Cincinnati, vice chairman, and William A. Starin, Ph.D., professor of bacteriology at Ohio State, Columbus, secretary. A dinner meeting was addressed by Dr. Charles A. Doan, professor of medicine and medical research at Ohio State, on "The Place of Bacteriology in Modern Medical Science."

### PENNSYLVANIA

**Personal.**—Dr. Thomas I. Cottom, Selinsgrove, has been appointed superintendent of the State Colony for Epileptics, Selinsgrove, to succeed Dr. Chester A. Marsh.—Dr. William M. Guilford, Lebanon, celebrated his one hundred and fourth birthday November 26.

**Annual Registration Due January 1.**—Every practitioner of medicine and surgery holding a license to practice in Pennsylvania is required by law to register annually, on or before January 1, with the board of medical education and licensure in the department of public instruction, and to pay a fee of \$1 or such fee as may be fixed by the department of public instruction. A practitioner who fails to register and who continues to practice is liable to a fine of from \$10 to \$100.

#### Philadelphia

**Society News.**—At a meeting of the Pennsylvania Physical Therapy Association, December 10, the speakers were Drs. Albert A. Martucci, on "Experimental and Clinical Observations in Cerebral Diathermy"; Frank Follweiler, Jenkintown, Pa., "The Value of Physical Therapy in Nose, Throat and Ear Conditions," and Thomas Lechner, "Value of Short Wave Diathermy in the Treatment of Sinusitis."—A symposium on the endocrine glands was presented at a meeting of the Philadelphia County Medical Society, December 9, by Drs. Eugene M. K. Geiling, Chicago; Leonard G. Rowntree, Philadelphia, and Emil Novak, Baltimore.—Dr. Leroy U. Gardner, Saranac Lake, New York, addressed the Pathological Society of Philadelphia, December 10, on "Silicosis and Related Conditions."—Among others, Drs. Ernest A. Spiegel and Charles M. M. Gruber addressed the Physiological Society of Philadelphia, November 16, on "Subcortical Activities" and "The Cardiac Action of Thiobarbiturates" respectively.—A symposium on diseases of the respiratory tract was presented before the North End Medical Society and the North Branch of the Philadelphia County Medical Society, November 19, by Drs. George M. Coates and Hobart A. Reimann.

#### Pittsburgh

**Personal.**—Dr. Camilla M. Anderson, Pittsburgh, has been appointed secretary of the Pennsylvania Mental Hygiene Committee of the Public Charities Association to succeed Dr. Leroy M. A. Maeder, Philadelphia.

**New Health Director Appointed.**—Dr. I. Hope Alexander has been appointed health director of Pittsburgh, according to the *Pittsburgh Medical Bulletin*, succeeding Dr. Ray P. Moyer. Dr. Alexander was graduated from the University of Pennsylvania Department of Medicine in 1906. He is chief of the medical staff of Passavant Hospital and professor of physical diagnosis in the school of dentistry of the University of Pittsburgh. During the World War he served as chief medical officer of a government hospital in North Carolina. In 1931 he was president of the Allegheny County Medical Society. For the last three years he has been president of the Pittsburgh chapter of the Izaak Walton League of America.

### TEXAS

**Annual Registration Due January 1.**—Every practitioner of medicine and surgery holding a license to practice in Texas is required by law to register annually on or before January 1, with the state board of medical examiners, and at that time to pay a fee of \$2. If a practitioner fails to renew his registration within sixty days after January 1, his license is suspended.

**Endowment for State Medical Library.**—The *Texas State Medical Journal* announces that Dr. Samuel E. Thompson, Kerrville, has designated the library of the State Medical Association of Texas in his will to receive a bequest of about \$50,000. The fund will bear the name of the giver and the principal will remain intact, the interest to be expended by the trustees to develop the library. Dr. Thompson is 65 years old, a graduate of the Kentucky School of Medicine, class of 1904. He is medical director and superintendent of the Thompson Sanatorium for tuberculosis, Kerrville, established in 1917.

### VIRGINIA

**Field Clinician Appointed.**—Dr. Jay M. Arena, associate in pediatrics at Duke University School of Medicine, Durham, N. C., has been appointed field clinician to conduct graduate courses in pediatrics under the auspices of the department of clinical and medical education of the Medical Society of Virginia. Dr. Arena conducted a graduate course for physicians in Nelson and Orange counties, with lectures and clinics at Livingston and Orange.

**Society News.**—At the meeting of the Fourth District Medical Society in Hopewell, November 10, Dr. William M. Bickers, Richmond, was the guest speaker, on "Treatment of Sterility in the Female." Other speakers on the program, all of Petersburg, were Drs. Charles S. Dodd on "Ludwig's Angina"; William B. McIlwaine III, "Lung Abscess in Children"; George H. Reese, "Significance of Abdominal Pain"; Herbert C. Jones, "Urinary Infections," and Hyman Cantor, "Treatment of Compound Fractures."—Dr. Gregory Zilboorg, New York, addressed the Richmond Academy of Medicine, November 10, on "The Organic versus the Mental in Psychiatry."

### WEST VIRGINIA

**Headquarters Remodeled.**—The headquarters of the West Virginia State Medical Association in the public library of Charleston have been remodeled. A private entrance has been cut and a new lighting system installed. The association's library and reception room have been redecorated and refurnished in modern style. The library contains about 1,200 volumes and has on file about seventy-five American and European medical journals.

### PHILIPPINE ISLANDS

**Plan to Improve Diet of Filipinos.**—The Philippine Council of Hygiene recently appointed a committee to gather information necessary for the formulation of concrete plans for improving the diet of the Filipinos, according to the *Journal of the Philippine Islands Medical Association*. Special attention will be directed to the diet of the army and to methods of producing cheap foods. Members of the committee are Manuel Roxas, LL.B., representing the National Research Council of the Philippine Islands; Drs. Isabelo Concepcion, representing the College of Medicine, University of the Philippines; Hilario Lara, representing the Council of Hygiene, and Attorney Lara.

### GENERAL

**Bequests and Donations.**—The following bequests and donations have recently been announced:

New York Medical College and Flower Hospital, \$50,000 by the will of the late Elias C. Benedict; \$5,000 by the will of the late George Leask. Hospital for Joint Diseases, New York, \$3,942 by the will of the late Charles L. Hoffmann.

Richmond Memorial Hospital, Princes Bay, Staten Island, N. Y., \$35,325, and Staten Island Hospital, Tompkinsville, N. Y., \$20,000 by the will of the late Frederick Ketteltes.

Montefiore and Mount Sinai hospitals, New York, \$8,115 each by the will of the late Henry Ollesheimer; \$2,500 each by the will of Jacob W. Gutman.

**News of Epidemics.**—About fifty cases of smallpox were reported in Dansville, N. Y., December 9. It was said that Hornell, eighteen miles from Dansville, had seven cases.—Eight cases of typhoid were reported in Swains, N. Y., a village of 100 inhabitants with no physician, newspapers reported December 8.—Schools were to open in Tulsa, Okla., November 30, after a month's vacation because of infantile paralysis; seventy-six cases had occurred in Tulsa County up to November 20, sixty-four of them in the city.—An outbreak of scarlet fever was reported at a state penal farm at Vandalia, Ill., November 18.—Scarlet fever appeared in fourteen public schools and one private school in Dallas, Texas, with thirty-nine cases in the first three weeks of November.—Thirteen recent cases of typhoid in Cecil, Washington County, Pa., were traced to contaminated water.—Newspapers reported thirty cases of diphtheria in an epidemic at Lost Creek, Harrison County, W. Va., November 19.

## Foreign Letters

### LONDON

(From Our Regular Correspondent)

Nov. 14, 1936.

#### Medical Coroners

At present the majority of coroners are lawyers but a minority are physicians. A committee appointed by the government to inquire into the law and practice of coroners' inquests made a report (*THE JOURNAL*, March 21, p. 1018) recommending that in future only lawyers should be appointed to the office of coroner, as the sifting of evidence requires legal training and a coroner without medical knowledge would be fully informed of the medical aspects of the case by the medical witnesses. The *British Medical Journal* objected to this recommendation. It admitted the desirability of the coroner having legal knowledge but thought it almost essential that he should also have medical knowledge. It pointed out that a large number of persons qualified for both professions. It has been the practice of the London County Council since 1919 to require from candidates for the position of coroner both legal and medical qualifications, but because of the recommendation of the government committee it proposes to discontinue the requirements of a dual qualification and to appoint only a lawyer. A deputation of the British Medical Association therefore submitted to the council a memorandum against this change. It pointed out that the coroners' act of 1926 enacted that no person could be appointed coroner who was not a lawyer or physician and that undoubtedly the representations of the association received due consideration when this law was passed. Since that time the association has urged the desirability of the dual qualification when practicable. All the London coroners except one hold the dual qualification and so do many of the coroners of the larger districts outside London, where they are of sufficient size to justify an appropriate salary. There has been no attack on doubly qualified coroners as such. Indeed, the inquests that attracted notoriety in the press and gave rise to the appointment of the government committee were conducted by coroners holding only legal qualifications. The report recommends that a "coroner should have training in forensic medicine." This is a cogent reason for appointing doubly qualified men. The association "cannot conceive how the possession of two qualifications—law and medicine—could be considered less desirable than one qualification—law—with only a smattering of forensic medicine." There is at present no dearth of doubly qualified suitable men for any appointment that may become vacant.

The importance of legal knowledge by the coroner has been reduced by recent legislation. Since 1927 he has been required to adjourn his inquiry after hearing the medical evidence when any person has been charged with murder, manslaughter or infanticide. Moreover, the committee recommended that his investigation of fact should be clearly distinguished from any trial or liability, whether civil or criminal. On the other hand, the medical aspect of the coroner's work is becoming more important. In London in 1934, 9,713 cases were reported to the coroner either through the police or through the physician who felt that he was not justified in taking the responsibility of issuing a death certificate, or by the registrar of deaths who did not feel justified in passing a certificate for registration. These cases are divided into those in which a coroner is compelled to hold an inquest and those in which, after a necropsy and inquiry, he can exercise discretion and on his own responsibility issue a certificate without an inquest. In London in 1934, 52 per cent. of the cases referred to all the coroners were dealt with without an inquest and as a result of a necropsy. Altogether in 1934 there were 6,248 necropsies. How does

a legal coroner read a report of a necropsy? However much he may have read textbooks he will never do so with the seeing eye of the physician.

#### Street Washing for Removing Poison Gas

This country, which once could rely for its safety on sea power, is now actively engaged in measures for defense against attack from the air, a possibility that cannot be ignored in the present disturbed international relations in Europe. The latest precaution is shown by a demonstration at Watford of the new Scammel street washer, which is effectual not only in fighting fires but in freeing the streets from poison gas after air raids. Out of the old fashioned watering cart has been evolved this highly efficient machine. It can spray water over a width of 90 feet and is capable of sending an arc of spray to reach the roof of a two story house. Streets where poison gas was present after an air raid would first be washed in this way and then under low pressure. At the same time the squeegees with which the washer is equipped would be brought into use for cleaning and to some extent for drying the road surface. The third stage of the decontamination of the streets would be to flush chemicals through the gullies. This would normally be done by connecting the nearest hydrant, but where the water main had been broken in an air raid the machine could do the work with its own power.

To aid the dispersal of nonpersistent gases the machine has a special piece of equipment in the shape of four "fishtails," which can take the place of the ordinary washing jets and which are mounted on ball joints to give freer movement. When these are set in motion they produce a fan-shaped sheet of water, which completely encircles the vehicle to a height of 30 feet and a width of 70 feet. Such a device makes it possible to purify the air and to wash the roofs of buildings and the sides of vehicles that have been contaminated.

#### An Earlier "British Medical Journal"?

It is generally supposed that the title "British Medical Journal" was first used in 1857 for a journal previously in existence for seventeen years which bore the name first of *Provincial Medical and Surgical Journal* and then of the *Association Medical Journal*. But *nil novum sub sole*. Our contemporary has discovered that the title "British Medical Journal" was announced for a new periodical at the end of the eighteenth century, though whether it ever appeared seems more than doubtful. A printed prospectus in the form of a four page leaflet was issued in London in 1798 and begins thus: "On the 1st of February, 1799, will be published, price two shillings, elegantly printed on fine Demy Paper, octavo size, containing at least six sheets of letterpress and embellished with one or two plates, to be continued monthly, Number 1 of a New, Useful and interesting Periodical Work, intitled the *British Medical Journal*; containing the Earliest Information on Subjects of Medicine, Surgery, Chemistry, Pharmacy, Botany and Natural History." The prospectus is lengthy and gives under ten headings everything that a medical journal could be expected to do—recent improvement and discovery in botany, chemistry, pharmacy and other medical sciences, an abridged view of the prevailing epidemics, "impartial histories of the most celebrated patent and other quack medicines," remarkable and authentic medical cases, descriptions of countries and places as to their salubrity, a review of all new publications in the various departments of medical science, and monthly tables of the variations in the wholesale price of drugs. One reads: "There is at present no monthly journal in the English language the professed and single design of which is to communicate accounts of every new observation and valuable discovery made from time to time in the different branches of medicine. An early circulation of intelligence so essential to the practitioner, as well as to society in general, has not been

attended to with the care which the importance of the object required." Though written nearly 150 years ago, when medical science was so different, this prospectus has a familiar ring. It reminds us of the lofty aims and the wants that have never been filled before, or at least so well filled as they will be, by some new journal about to be or just launched. The subsequent failure to realize high hopes is also not without more recent parallels. But we have advanced in one way. Such prolixity would not be possible in an editorial announcement today, though the same could not be said of the ordinary medical article.

### The Training of Factory Nurses

The increased attention to industrial welfare has led to the appointing of physicians and nurses to factories. But it is not every factory that can afford to employ both, and a nurse who works alone has considerable responsibility. Her work consists not only in the treatment of accidents and minor injuries but in advice as to health. In the case of processes involving special risk or strain she may have to carry out special treatment under medical supervision. She therefore requires special training. For the past two years the College of Nursing has provided special courses of instruction for nurses who undertake factory work.

### PARIS

(From Our Regular Correspondent)

Nov. 21, 1936.

### The Surgical Congress

IN THE JOURNAL, November 14, page 1647, the reports read at this year's French Surgical Congress were referred to. In addition to the participants previously cited, the subject of ovarian grafts was discussed by other speakers. Mayer of Brussels disagreed with the reporters in saying that intramuscular grafts were not successful in female dogs. His own experiments showed that such was not the case and that if the grafts did not survive it was due to a faulty technic. He prefers instead of placing the graft clinically in the abdomen to insert it into either the rectus (abdominal) muscles or the subcutaneous or retromammary connective tissue. In cases in which the uterus had been conserved, the ovarian grafts were successful in 88 per cent of the cases. Menstruation recurred regularly for several years. In supravaginal hysterectomy cases he could cite only 50 per cent successes.

Desmarest of Paris emphasized the necessity of conservation of the tubes and ovaries in cases of hysterectomy for fibroids. Eighty per cent of his patients had no disturbances following such a procedure. The estrogen content of the urine in such patients is equal to that of women having normal menstruation. This is also true of the estrogen content of the blood. In uterine fibroids, if myomectomy is impossible, only a supravaginal hysterectomy with conservation of the tubes and ovaries is indicated.

The discussion on the subject of pneumonectomy was continued by Rist of Paris, who stated that the present tendency of regarding bronchiectasis as a benign disturbance is too prevalent. Bronchiectasis always ends fatally, after a prolonged clinical course. If, however, bronchiectasis is treated during an early period of its development, a thoracoplasty, with in some cases also a phrenicectomy, can be of great benefit.

Among other papers read was one on foreign bodies in the esophagus, by Jean Guisez of Paris, who has observed 530 cases. The most frequent foreign bodies (200 cases) that lodge in the upper portion of the esophagus are small bones (especially those of fishes). In seventy-two patients a set of false teeth had been swallowed, and next in frequency were buttons, open safety pins and coins in infants. He had removed, with the aid of esophagoscopy, an open safety pin from a 6 weeks old child. The most reliable clinical symptom of foreign bodies

in the esophagus is complete inability to swallow either liquids or solids. At times there is a complete absence of any clinical signs in children who have swallowed metallic bodies, because these are well tolerated. This is not true of small bones, the lodgment of which is apt to be followed by septic complications either in or outside the esophagus. Endoscopy has greatly facilitated the removal of foreign bodies in the esophagus. His mortality in 530 cases was only 2 per cent, and he was unable to deliver the foreign body in only 1 per cent. In the last 220 cases he had only one death and no failures of extraction. The death occurred in an adult whose false teeth had lodged so firmly in the upper part of the esophagus that several attempts had been unsuccessful before the patient was seen by Guisez.

Ferey of Saint Malo (France) reported eighty-two cesarean operations performed during the past six years. Of these, seventy-six were of the low type, one of the high and five a section followed by hysterectomy. He has performed the low cesarean operation in eighty-eight cases without a death and believes that this technic has innumerable advantages over the high operation.

Judet of Paris has been obliged to operate only once in 300 cases of supracondyloid fractures of the humerus in children. If the reduction can be made under fluoroscopic control within a few hours after the accident, complete approximation of fragments is always possible. The elbow should never be placed in extreme flexion because of the danger of interference with the blood supply (brachial artery) and resultant Volkmann contracture. Operation is indicated only if nerve or vascular complications exist.

### Familial Intolerance of Mercury by the Kidneys

At the June 19 meeting of the Société médicale des hôpitaux, Tzanck and associates reported two cases in the same family of intolerance of mercury by the kidneys. A man, aged 44, received injections of mercuric oxycyanide for hereditary syphilis. Two hours after the first injection, the previously existing headache became more severe and the next day an edema involving both lower extremities and a very marked albuminuria appeared. Following a second injection the patient became comatose. The injections were discontinued and all symptoms disappeared in a few days. Since then a bismuth treatment has been given without any further signs of renal intolerance. The daughter of the patient showed evidences of hereditary syphilis. Following a series of mercury injections when she was 5 months old, a hematuria appeared. This recurred when an ointment containing yellow mercuric oxide was given at the age of 4 years. Thus there were two members of the same family who manifested a renal intolerance to mercury.

### Experimental Syndrome Resembling Obliterating Thrombngitis

At the July 1 meeting of the Académie de chirurgie, Leriche and Froehlich described experiments on rabbits, like those of Maggi and Mazzochi, reported in 1933, in which lesions like those observed in obliterating thrombngitis were observed after transplantations of fragments of the adrenal. This was done every four days by Leriche and Froehlich. In the controls, in which testicular and ovarian grafts were used, the veins and arteries remained intact. In all the rabbits in which fragments of the adrenal were transplanted, both arterial and venous lesions appeared which resembled greatly those seen in human beings. The lesions were slight when only six to ten grafts were used but very marked when twenty or more were employed. The chief changes observed were considerable narrowing of the arterial lumen, general contraction of the vessel, proliferation of the endothelium, which is very thick in places, with increase in the elastic fibers, the latter two changes forming marked salients into the lumen. At this point, a thrombus

formed, and one could see a sclerotic tissue replacing the muscular fibers. In certain veins the same changes excepting the thrombus formation were visible. In a rabbit that had received thirty-nine grafts and been kept under observation for a little over six months, the femoral artery was found to be completely occluded and a persistent ulcer appeared on one of the paws. Fontaine had previously noted similar thromboses of veins and arteries following daily injections of cholesterol over a period of six months. If one recalls that the medullary portion of the adrenal plays a fundamental part in the metabolism of the cholesterol, it seems probable that thrombangitis with arterial and venous lesions is the clinical expression of an adrenal disease. This agrees with the results obtained by Leriche by removal of the adrenal or division of the splanchnics, which partially denervates the adrenal.

### The Organization of Health Centers

The medical profession, through its Federation of Medical Syndicates or Unions, has proposed to the secretary of public health to take charge of his plan of organizing health centers all over France. The object of the federation is to keep this feature of social medicine in the hands of the practitioner instead of permitting it to be administered by officials of the department of public health. There has, of course, arisen some opposition within the ranks of the profession, but this has been overcome, since it is evident that, unless the present socialist government is given cooperation in its program, the alternative will be state medicine and the disappearance of private practice.

In the October 4 *Concours médical* appeared an impartial discussion by Dr. Fischer of such cooperation, stating that, considering the rapidity of social revolutions, this offer of cooperation is the only way of safeguarding traditional medicine and conciliating its needs with the requirements of hygiene and prophylaxis that those who wish to socialize medicine demand to protect the public.

The manner in which social insurance was forced on the profession has compelled physicians, especially the younger ones, to adapt themselves to new conditions which were formerly rejected. Fischer believes that the assumption of the task of preventive medicine should be carefully worked out lest failure to carry it out properly be followed by worse conditions than exist at present. The medical profession, having had its experience with the manner in which many promises were not kept by the social insurance authorities, should present a united front on the present question of cooperation in preventive medicine.

The plan is not to be tried out in large communities like Paris, which present complicated problems, but in a smaller department or county to begin with. The majority of the work can be carried out in the offices of practitioners. It is to be only of a diagnostic nature, so that the patient can still choose the physician he wishes to carry out the treatment. A committee of coordination composed of physicians and public officials ought to meet every three months to supervise the work. In larger communities it is planned to have diagnostic centers fully equipped with all modern diagnostic resources. This plan of cooperation is soon to be submitted to the secretary of public health.

### Protest Against Foreign Physicians in France

A want ad for a position as medical inspector in the social insurance organization recently appeared in the *Concours médical* and there were eight applicants for the position. In an editorial appearing in the September 19 issue of the journal the writer, Dr. J. Noir, asks whether this relatively large number of applicants for such a position does not signify that many middle-aged physicians are seeking a haven in which they would no longer have any worries regarding their income. The advertisement stated that only those need apply who had been

in practice at least ten years. This would exclude as applicants recent graduates who had not yet built up a practice. The rôle of foreign-born physicians practicing in France, as revealed by Dr. Queyrriou at a meeting of the syndicate of physicians in the northern suburbs of Paris, is quoted in the editorial. More than one fourth of the practitioners in Paris and its suburbs are non-naturalized foreigners. This percentage was only 8 in 1911 and 10 in 1931. Fifteen per cent of the physicians in all France were foreigners in 1935. At the Faculté de médecine, the largest medical school in France, there were 1,530 foreigners out of a total of 3,332 students; 689 of the 1,530 foreign students were preparing to pass the examinations for licenses to practice in France and the remainder wished only to have an honorary "diplôme d'état," which does not entitle them to practice in France or its colonies unless they pass additional examinations, which some of them will probably try to do. During the first six months of 1936, 163 foreign physicians registered their state licenses in Paris, as compared with 124 of French birth. The present socialist prime minister is quoted as having stated that about a thousand physicians who have sought refuge in France will be granted permission to practice here. An effort is being made by the various medical syndicates (associations to protect the interests of the profession) to insist on the enforcement of a law which will prevent any foreign-born physician practicing in France and its colonies during a period of ten years after naturalization. Noir regards the invasion of the profession by foreign physicians as the most important factor in the present medical crisis here.

### University Diploma Falsely Registered

There is quite a sharp distinction in France between a university diploma of a medical school and the state diploma, which alone confers the right to practice. Following the passage of the new license laws in 1933, every diploma was verified by representatives of the government and of the medical profession.

A foreigner, who had passed only the examinations required in order to obtain a university diploma, had succeeded in having it registered by the police department (where all diplomas must be registered) as a state diploma, conferring the right to practice. Many foreigners, especially since the World War, have entered medical schools in France and followed the courses leading to the university diploma. The latter is often of considerable value in the foreigner's native country in obtaining the state license. At one time there were a number of North and South American and European medical students who had not been eligible to admission to schools at home and expected their studies in French universities to serve as credits toward obtaining a state license at home. This practice has been entirely abandoned in most European countries, with the result that the number of candidates for a university diploma has greatly diminished here.

The possessor of the university diploma, in the case cited, refused to discontinue practice, on the ground that his diploma had been duly registered, although the registration had been done by a clerk who did not realize the difference between a university and a state diploma. To obtain the state diploma, the student not only must pass all the examinations at the respective medical school, as is required also of the candidate for a university diploma, but must have received the bachelor of arts degree from a French university. The latter requirement has been the chief stumbling block in the past for American physicians who wished to practice here. According to the present laws (since 1933) only those foreigners who were practicing in France and had a state license could continue to do so.

The government authorities have just decided that the physician who had only a university diploma and had it registered as a state diploma was not entitled to practice here. This decision will put an end to any attempts by foreigners, who

have flocked to France in large numbers recently, to utilize their university diplomas, which are of purely honorary character, to remain here.

#### Plea for a Single Medical Diploma

As explained previously, a medical student in France can elect to graduate with a university diploma (*diplôme universitaire*), a purely honorary one, which does not entitle its holder to practice in France or its colonies, or to graduate with a state diploma (*diplôme d'état*), which carries with it the right to practice without the obligation to pass any other examinations than those given by the faculty of the medical school. The only difference between these two forms of diplomas in France is that the candidate for a state diploma must have received a bachelor of arts degree from a French university. Those granted by universities of other countries are not considered valid here. Many protests are being made against this dual system and sooner or later it will be discarded in favor of a single diploma to be followed by a state board examination for all candidates, as now exists in the United States, Germany and other countries. A writer in the *Revue moderne de médecine et chirurgie*, Dr. P. Gallois, makes a strong plea for the granting of only one type of diploma and a subsequent state board examination. Such a licensing board should have full power to refuse permission to practice to those who are not French citizens, possess a bachelor of arts degree, have had three years' military service and have been naturalized a minimum of ten years. Only in this way can the overcrowding of the profession here by foreigners during recent years be checked. This would put a stop to the present method so often employed by foreigners of changing a university to a state diploma by simply passing the examinations for the bachelor of arts degree at a later date.

#### "Mock" Night Attack of Enemy Bombers

For the first time since the World War, Paris extinguished its myriad lights and shrouded itself in darkness, October 16, in defense against an air attack. While supposed enemy bombing planes circled over the obscured city, dropping flares representing destructive explosives and poisonous gases, fire engines sped through the dark streets to combat "fires," and ambulances rushed the "gassed and injured" to first aid stations. All traffic was halted, and automobiles and other conveyances remained motionless while the hypothetical attack was in progress. Notice of the impending attack was given by the screeching of seventy sirens. The center of the sham air raid was in the Latin quarter. Red Cross nurses and stretcher bearers protected by gas masks picked up the wounded and transported them to hospitals, while disinfecting squads purified the air. Observation planes passed overhead to measure the extent to which the city had become invisible. Experts declared that the actual tests worked out with minute precision, and relief squads operated efficiently throughout the city.

#### Transfusion of Refrigerated Citrated Blood

Reference has already been made in these letters to the success in using blood for transfusion which has been placed in a refrigerator, following dilution with sodium citrate. Professor Jeanneney of Bordeaux was the first to suggest this method of conserving blood, which has been extensively employed in southwestern France and in Russia. In the latter country, Bagdassarov of Moscow has employed this method 2,400 times, and Filatoff and Bopp of Petrograd 1,200 times.

Tullien-Neroz, a pupil of Jeanneney, in a thesis submitted for graduation in 1935, called attention to the manifold advantages of the conserved blood method. The practitioner has at his disposal ready for use blood that has been strictly controlled in advance as to grouping and the presence of such diseases as syphilis and malaria in the donor. Such blood is

also immediately available for the purpose of immunotransfusion. The blood as soon as received from the donor is mixed in a 250 cc. flask containing 20 cc. of a 5 per cent solution of sodium citrate. A tag on the flask indicates the name of the donor, the group and the date on which the blood was taken. The flask is then placed in a refrigerator at a temperature of 2 C. (35.6 F.). The blood is available for immediate use during a period of eighteen days and even longer. The changes undergone by the refrigerated blood are of no importance clinically. The method avoids having donors on call and has the advantage of being available in emergency cases.

#### International Congress of Physical Education in 1937

At the Paris Exposition of 1937, an International Congress of Physical Education and Sport will be held during the week beginning July 14. The National Committee of French Sports and the president of the committee of organization, Dr. Collect, will have charge of the program. The object of the congress is to interest the French medical profession in encouraging boys and girls to take up sports in a more active manner than is at present the case. Intercollegiate competition is but little developed here, in spite of the fact that an assistant secretary of sports position in the cabinet has existed for some time.

#### Souvenirs of the Charité Hospital

Reference has been made in these letters to the demolition of the historic Charité Hospital in Paris in order to provide space for the new laboratory buildings of the medical school. The *salles de garde* of the older Paris hospitals are of great interest to those interested in medical history. The *salle de garde* of the Charité, or room in which the interns on duty for emergency cases assembled, sheltered during its 300 years of existence many of the most famous medical men of France during their internship at the Charité. On the walls of this particular *salle de garde* were a number of paintings by the best French artists of the respective periods. One of the most interesting of these paintings shows Velpeau and his intern chasing a quack, who even in those days guaranteed to cure cancer, from the Temple of Science. As a result of the initiative of Dr. Mourier, director of the public hospitals of Paris, all these paintings, which will be of great value to those interested in medical history, have been placed in a museum on the *de la Tournelle* in the center of Paris.

#### Laignel-Levastine Elected to Academy

Election as a fellow of the *Académie de médecine* is considered one of the highest honors that can be conferred on a member of the profession. At a recent meeting of the *Académie*, Dr. Laignel-Levastine of the *Hôpital Lariboisière*, neurologist and medical historian, was elected. He is professor of the history of medicine at the medical school of the University of Paris and secretary of the International Society of the History of Medicine.

#### Death of Dr. Jean Charcot

The sad death of Dr. Jean Charcot, captain of the vessel *Pourquoi Pas*, and all the crew except one, by shipwreck on the coast of Iceland during his last scientific expedition, was reported a few weeks ago in the daily papers. Jean Charcot was the son of the late Prof. Jean-Martin Charcot, the internationally known neurologist of the *Salpêtrière*, and was born in Paris in 1867. Following an internship in the Paris hospitals, he became chief of clinic at the *Salpêtrière* but soon ceased to practice and began his first oceanographic expeditions. He was especially interested in the study of geographic conditions at the north pole and in 1912 was given the grand medal of the French Geographic Society. After the World War he organized another expedition and brought back a large number

of important observations. As a recognition of his contributions to science he was elected a fellow of the Academy of Science and Academy of Medicine. Following the death of Dr. Charcot and his companions on his last polar expedition, the French government has decided to pay the highest honors in the form of a national funeral to the dead heroes as soon as the remains arrive in Paris. A special medal to commemorate the work of Dr. Charcot has also been ordered.

## BERLIN

(From Our Regular Correspondent)

Oct. 26, 1936.

### International Congress of Otorhinolaryngologists

The third International Congress of Otorhinolaryngologists was held at Berlin in August. Professor von Eicken presided. About 800 delegates, German and foreign, participated.

The first speaker, on the topic "Radiotherapy in Malignant Tumor Cases," was Berven of Stockholm, who is accustomed to treat malignant tumors of the oral cavity and of the mesopharynx with radium and, much less frequently, with roentgen rays. Because of the relatively large supply of radium available at the Stockholm "Radium Home" it is possible to administer telerradium therapy by means of "radium guns" which contain from 3 to 8 Gm. of radium sulfate. This offers the widest range of possible approaches as, for example, multiple field irradiation and cross-fire irradiation. Daily and total dosage are adapted to the requirements of each case; in addition, the general condition and age of the patient, and the best type of adjuvant treatment to be introduced are all considerations. The Stockholm men have also worked out a therapeutic program under which early stage syphilis cases have decreased from 60 per cent to 35 per cent within a ten year period. Late stage syphilis, on the contrary, has increased from 40 per cent to 60 per cent during the same period. This shows how rapidly and successfully the early stage cases are being combated. Naturally the excellent organization of the Stockholm institution has contributed to these favorable results.

Hautant of Paris undertook, in collaboration with Coutard, the treatment of cancer of the larynx at the Curie Institute, Paris; 25 per cent of 122 such cases could be considered cured at the end of a nine year follow up. Choice of irradiation or of operative treatment was made on the basis of the situation and type of the cancer and the patient's general condition. Irradiation is usually indicated if infiltration has not yet begun. If the vocal chords are still movable, it may be assumed that the carcinoma is not yet infiltrating. Otherwise the efficacy of the 'roentgen rays' is dubious. According to Hautant's experiments "the epidermal epitheliomas, exophytic and vegetative in form," the cells of which have undergone only a suggestion of epidermoid alteration or none whatever, may be effectively irradiated. Other carcinomas of the infiltrating, ulcerating type are refractive to the rays, particularly if horny pearls are present in the altered epidermoid tissue.

Maisin of Louvain obtained his optimal results if the malignant growth had its seat in a tonsil or the distal two thirds of the tongue. Contrary to expectations, a combination of surgical therapy and radiotherapy yielded rather unfavorable results in the treatment of metastases in the lymphatics. Here roentgen treatment alone seemed to be advisable. Telerradium therapy appears most favorable if a cartridge containing 7 Gm. of radium is used.

Torrigiani of Florence applies protracted fractionated irradiation in cancer of the larynx and also in treating the lymph nodes. In cases of tumors within the accessory nasal cavities he recommends radiosurgery: a wide opening should be effected through the healthy palate in order that the region of the tumor may be treated by the most delicate technical procedures and any recurrence may be detected. If a malignant tumor is

situated in the ethmoid bone, an eye must be sacrificed if necessary in order that the focus may be more directly approached.

Schinz of Zurich determined by a vast amount of experimentation that better results were obtainable with the protracted-fractionated method of irradiation. To be sure, the sum of the end results of irradiation is not yet numerically as impressive as the sum of the results of operative treatment, but one must remember that the data on operative treatment have to do exclusively with more favorable cases.

Vogel of the Berlin clinic discussed the curative treatment of carcinoma of the vocal chords by a combination of operation and irradiation (thyroid cartilage fenestration) which, he, said, is effective in an average of 90 per cent of such cases. In a large proportion of the cases, permanent cure has been determined by follow up of from five to seven years' duration. In 40 per cent of other cancers, likewise situated within the larynx, cure was effected by protracted fractionated roentgen irradiation and without surgical intervention; here, too, numerous cases exhibited no signs of recurrence after the lapse of more than three years.

The second major topic was "Electro-Acoustic Apparatus for the Testing and Improvement of Hearing." Langenbeck of Leipzig spoke of the advances made within the last twenty years through electro-acoustics. Electrical testing of hearing with the audiometer belongs today among the indispensable tools of clinical diagnostics. In the realm of auditory prosthesis, development as far as medical research is concerned is now essentially a question of technic. In this connection Pohlman of Omaha demonstrated a simple yet obviously effective hearing prosthesis. The theory of this device proceeds from anatomic assumptions. This prosthesis is soon to be examined at the Berlin clinic.

The third topic was "The Influence of the Constitution on Disorders of the Ear, Nose and Throat." It would seem that constitutional factors play a part in the manifestation of carcinoma in the hypopharynx and esophageal orifice of females.

### German Institute of Psychotherapy

The German Institute of Psychologic Research and Psychotherapy (Deutsches Institut für psychologische Forschung und Psychotherapie) has been established with the sponsorship of the National Ministry of the Interior. The membership is composed of representatives of the Pan-German Society of Psychotherapy, the German Psychoanalytic Society, the Künkel cooperative group for "Applied Study of Character" and also other well known psychotherapists. The three last named organizations will function within the institute as cooperative societies. The duties of the institute shall be (1) research, (2) educational and teaching activities and (3) maintenance of a polyclinic for the indigent. The institute begins its work with the winter semester 1936-1937. The director of the institute is Prof. Dr. M. G. Göring, president of the Pan-German Medical Society of General Psychotherapy.

### Blood Tests for Alcohol in Traffic Accidents

The minister of the interior recently ordered blood tests for alcohol in connection with traffic accident cases. Such blood tests were first experimentally performed under the auspices of the Berlin police administration. On the basis of these experiments it is now stipulated that examination be made of all those persons involved in traffic accidents who are reasonably suspected of being under the influence of alcohol.

For determination of alcohol in the blood the micromethod of Widmark is indicated as a well known and reliable procedure. As soon as possible following the accident the specimen is drawn from the ear lobe or finger tip and collected in specially prepared glass tubes. The Widmark method has received recognition in an amendment to the criminal procedure

statute. In order to save expense the withdrawal of the blood specimen and the clinical examination are considered a part of the duties of the regular police physician. In order that the greatest possible exactitude and certainty may be obtained in the medical establishment of sobriety or inebriation, a medical examination must in each case be carried out and the observations properly recorded on questionnaire blanks. This procedure is particularly important if the alcoholic content of a suspected person's blood is not great enough to establish an alcoholic influence in the absence of other evidence. An especially valuable feature of the Widmark method is that by it not only the influence of alcohol but a state of sobriety may be determined; this may have a decisive bearing on the release from custody of a suspected person. Since the alcoholic content may be preserved for several weeks in the specially prepared glass tubes, the possibility of a later central examination in the main laboratory of the government hospital is guaranteed the police officials.

### Marriage Prospects of Professional Men

*Wissen und Dienst*, the publication of the German student bodies, has taken up the problem of marriage prospects for young professional men. It was stated as an established fact that university trained men have "the fewest children of any group of the population." The causes of this circumstance are being investigated particularly with reference to the situation, peculiar to the present, which has been created by the requirements of the labor service and of the two-year military service. After four years of elementary school and nine years of secondary school, the average "prep" graduate will be 19 years old. Then after fulfillment of labor and military service he enters the university at the age of from 21 to 22. If his professional course is considered as requiring a minimum period of from four to six years (medical students must complete at least eleven semesters of study), the average age of candidates for the final academic examinations will be from 26 to 27 years. All prospective physicians, jurists, government officials and so on are compelled to put in a further period of preparatory service, which may be as long as three and a half years and during which at best only a minimal compensation is received. At the time of his entry on a regular professional career the man is thus generally from 29 to 30 years old, and even then his annual income is scarcely sufficient to support a family. The minister of the interior, seeking to remedy this deplorable state of affairs, recently announced that henceforward the usual thirteen year period of general extensive education, four years of elementary and nine years of secondary school (gymnasium), shall be reduced to a twelve year period.

### Short Wave Therapy in Gynecology

Prof. Heinrich Guthmann, assistant at the university gynecologic clinic at Frankfort, recently addressed the medical society of that city. He prefaced his remarks by an objection to the term "ultrashort waves." In actual practice, radiations the wavelengths of which may vary from 3 to 15 meters are administered. Only partially understood are such biologic effects as displacement of the hydrogen ion concentration toward acidity, stimulation of phagocytosis, increase in the capillary permeability, the weakening of bacterial toxins and the reactive increase of calcium in the tissue. The complete picture corresponds to that presented by an increase in the tonus of the vagus. Because of these biologic alterations and of the active hyperemia produced by the penetrating irradiation, the procedure is applicable in all disorders in which these alterations are the desiderata and above all in inflammatory processes. In practice the local treatment, the artificial production of fever and the treatment of the superordinated organ are differentiated. In general it has been demonstrated that, in contrast to diathermy, results are favorable, the fresher the processes.

Furunculosis, Bartholinitis, perimetritis and adnexitis are all well influenced and favorable effects in gonorrhea have been noted. Gonorrhea of the mucosa is apparently not influenced. In genital tuberculosis this type of treatment is better endured than any other heat therapy, according to experimentation at the Frankfort gynecologic clinic. Only in those carcinoma cases in which fever was present was the treatment administered. The ill effects reported from other sources was not observed; on the contrary, there was an alleviation of pain. Neuralgias and spasms of various types react well. This treatment is indicated in inflammations of the gallbladder during pregnancy, in gonorrheal arthritis and in arthritis ovaripriva. In the last named disorder it should be combined with the administration of estrogenic preparations. The favorable results have not yet been given statistical representation. Favorable effects on the diseases have, however, been observed and the period of treatment has been shortened. Likewise of particular note are the successes achieved in cases which hitherto have been futilely treated by other methods. The treatment is seldom contraindicated. As to the method employed, the dosage in the absence of a physical measuring standard still depends in the last analysis on the thermic sensations of the patient. Individualization and consideration of the possible formation of an abscess may likewise determine the dosage and it should be assumed as axiomatic that the fresher the process the smaller the dosage to be introduced at the beginning. The method of administration will also vary according to the circumstances of a case; it depends not so much on the attainment of a maximal temperature as on the stimulation of a defense reaction in the organism. As Guthmann emphasized in his closing remarks, short wave therapy is to be regarded as a valuable physical therapeutic development. The technic must now patiently be brought to perfection.

### New Procedures in Ophthalmology

Professor Jess of Leipzig recently discussed in the medical society of that place innovations in therapeutic procedure. In 1929 Heine of Kiel described the adhesive glasses which he had brought to perfection and which were to be worn beneath the eyelids for the correction of anomalies of the corneal cone and of refraction. Meanwhile Professor Jess, first at his Giessen clinic and later at Leipzig, has been able to correct a greater number of cases of the same nature also by means of the adhesive glasses. His experiments established that a distinct correction is possible but that not all patients are adaptive to the wearing of the glasses. Hypersensitive persons with prominent eyes and tense lids do not become accustomed to the device. Other persons are wont, after appropriate instruction and a period of adaptation, to become entirely reconciled to the adhesive glasses. Irritations occasionally encountered never assume a serious character; slight opacities of the corneal epithelium tend to correct themselves after a longer wearing of the glasses. Artists, sportsmen and others who shy at the wearing of spectacles are amply recompensed by a trial of these adhesive glasses.

Jess discussed among other new operative procedures the lacrimal sac operation of Toti, by which the tear flow is restored. Only in the most extreme cases should the lacrimal sacs be radically removed; namely, if the presence of a corneal tumor demands that the source of infection be immediately shut off. In all other cases the attempt should be made to render the lacrimal sac again capable of function by a wide communication with the nose. The therapeutic effects of this last named intervention are excellent but rarely is there any later coalescence and then usually only if the postoperative cure is inadequate or faulty.

The new Elschnig method of extraction of cataract in the capsule and of the removal of a luxated lens by electrocoagulation

lation is an advance over the older procedures, as in the latter, after the tearing open of the capsule, the content of the capsule sac was more or less completely removed and extensive formations of secondary cataract often took place necessitating further operative interventions. Jess therefore resorts to the older methods only in overmature and soft cataracts in which the lens normally cannot be enucleated with the capsule. For all not wholly mature cataracts in which the capsule still possesses a greater solidity, intracapsular operation is preferable and the same is true in cases requiring extraction of a luxated lens. Following excision of the cataract, the lens, which has become firmly attached to a needle electrode by electrocoagulation, may be easily removed from the eye, a procedure that formerly was possible with the aid of loops and forceps.

### ITALY

(From Our Regular Correspondent)

Oct. 15, 1936.

#### Light as a Cause of Disease

Prof. Guido Guerrini, head of the pathologic institute of Bologna University, in a recent lecture to the army physicians spoke on light as a factor causing disease. Light is a stream of radiating waves varying in length from 4,000 angstrom units for the violet to 8,000 for the red. The action of light may be direct or indirect. Direct action induces local phenomena such as hyperemia. Indirect action induces general phenomena. The action of light depends on individual physiology, constitution, age and sex. Blond persons are forty times more sensitive to light than persons with a dark complexion. The elder are more sensitive than children and the latter more than youth. Men are twenty times more sensitive to light than women. The sensitivity of women increases during pregnancy and menstruation. The clinical forms of light disease may be phototraumatic, photodynamic, photobiologic and photo-anaphylactic. In phototraumatic light disease, the skin struck by light reflects a part but not all of the radiations. The remaining part enters the tissues. Through stimulation of the cutaneous nervous ends, hypercemia, xeroderma, senile keratosis and epitheliomatosis are induced and local inflammation results from the mobilization of histamine from the skin into the tissues and from nutritional alterations of the tissues. Light induces an accumulation of cholesterol in the uncovered surface of the skin, which facilitates metaplasia. Photodynamic light diseases are those in which light acts through catalyzing agents. The mechanism of production of photodynamic phenomena are not yet clear. Robuschi showed recently by experiments that light filtered through solutions of methyl violet kills mice, guinea-pigs and rabbits. Robuschi's phenomenon is important. Many researchers on this field have concluded that photocatalyzing agents have an inhibitive action. According to the speaker the action depends on the quantity: Large doses of photocatalyzing substances have an inhibitive action whereas small doses have a stimulative action. There are endogenous and exogenous photocatalyzing substances. The bile pigments and hematoporphyrin are endogenous photocatalyzing substances. Eosin, methylene blue, neutral red and the salts of quinine are exogenous. Pellagra, according to modern conceptions, is considered a photodynamic light disease resulting from endogenous photocatalyzing substances (indolethylamine, phenylamine and, perhaps, hematoporphyrin) rather than from the eating of maize. Photobiotrophic light diseases are those in which light plays a part, either by stimulating specifically the action of a virus or by inhibiting the defensive resistance of the body. Spring turunculos and staphylococic impetigo (in which light increases the virulence of staphylococcus) as well as lichen and psoriasis are forms of photobiotrophic light diseases. In actinophylactic light diseases light renders the body either more

sensitive to a bacterial protein or more liberal in producing new antigens. Solar urticaria frequently has the character of a papulous dermatitis in which histamine is probably the antigen.

#### Vaccines and Serums for Africa

The Istituto Sieri-Vaccinogeni of Asmara is concerned with the preparation and distribution of serums and vaccines. From July 1, 1935, to April 30, 1936, 453,067 doses of smallpox vaccine were distributed in Africa. At present, 50,000 doses of the vaccine are weekly sent by air service to African sanitation centers; 44,276 head of cattle were vaccinated against plague in a month. Mortality from the plague is now 0.96 per cent. The laboratories of the institute are located several kilometers from Asmara. The institute has 3,000 heads of well fed cattle grazing. To increase the work of preventive immunization and also for making compulsory vaccination in African children, laboratories for the production of smallpox and antirabic vaccines are established at Addis Ababa. Some natives know about the benefits of vaccination and when Italian troops occupied the country they brought presents to the Italians asking to exchange them for the administration of smallpox vaccine.

#### Laws to Encourage Large Families

Regulations were recently approved by the council of ministers to provide married couples who have children more opportunities than couples without children. Couples will be given prizes by the provincial and the municipal authorities for having children. There will be a special prize from the state for mothers bearing twins. Parents having eight or more children are to be excluded from the payment of school taxes. Certain special licenses, which were previously necessary for the marriage of soldiers, municipal workers and women working in psychiatric institutions, have been abolished.

#### International Dermatologic Exhibit

Professor Tommasi, head of the syphilis and skin clinic of the University of Palermo, introduced a motion to the ninth International Congress of Dermatology which resulted in the establishment of a central office for study and interchange of scientific material. The office is called the "Centrum Commutatorium Dermatologicum," with headquarters during five years at the Budapest clinic. The work of the office will include the compilation of collections of scientific material, unification of scientific nomenclature and the teaching of dermatology. Collections will be made of photographs, microscopic slides, paraffin inclusions, wax preparations and similar material prepared in relation to rare diseases and those recently discovered and will be exhibited at the central office and its branches by changing the collections in the different branches for spreading the knowledge in different places.

### Marriages

ARNOLD PEEL MULKEY, Millen, Ga., to Miss Victoria Davis of Morehead City, N. C., in Kingston, N. C., August 12.

FREDERICK McCULLOCH MORRISON, Lynchburg, Va., to Miss Gertrude Davis Hancock of Beaufort, N. C., recently.

CHARLES GORDON MERRICK, Fort Myers, Fla., to Mrs. Elizabeth Woolslair Page in Jacksonville, September 8.

RUDOLPH DAVID MARTIN, Nanticoke, Pa., to Miss Helen Irene Gombar of Throop, August 7.

THOMAS LAWMAN LUCAS to Miss Jane Hill Agnew, both of Charleston, S. C., August 31.

WILLIAM C. McCONNELL to Miss Gladys Behlmer, both of Sunman, Ind., September 24.

JOHN I. LIMBURG JR., to Miss Frieda Schere, both of Cedar Bluffs, Iowa, recently.

PHILIP L. KURTZ to Miss Jane Elizabeth Walker, both of Indianapolis, July 15.

## Deaths

**Henry J. Gahagan** © Chicago; Rush Medical College, Chicago, 1893; practiced in Elgin, Ill., from 1897 to 1914, where he served as commissioner of health from 1897 to 1901, and city physician from 1901 to 1909; member of the American Psychiatric Association, member of its National War Work committee, 1917-1918, and chairman of its occupational therapy committee in 1918 and 1921; member of the medical house staff, attending physician, Elgin State Hospital, from 1893 to 1897, and superintendent from 1914 to 1917; medical director of the Mercyville Sanitarium, Aurora, since 1917; attending physician, consultant on the staff and member of the insanity committee of the Cook County Psychopathic Hospital; in 1916 was appointed by the board of administration of Illinois to visit the state institutions in New York, Pennsylvania, Maryland, Massachusetts and Ohio and report as to the industrial pursuits of patients; aged 68; was killed, November 10, when he was struck by an automobile as he alighted from a bus.

**John Fairbairn Binnie**, San Diego, Calif.; University of Aberdeen Faculty of Medicine, Scotland, 1886; began practice in Kansas City, Mo., in 1889; member of the Missouri State Medical Association; secretary of the Section on Surgery and Anatomy of the American Medical Association, 1908-1909; at one time professor of surgery at the University of Kansas School of Medicine, Kansas City, Kan.; formerly on the staff of the Kansas City (Mo.) General Hospital; organized Base Hospital 28 as a Red Cross unit before the war and directed the unit in France until he was assigned as surgical consultant to the third army corps; member of the American Surgical Association and the Society of Clinical Surgery; fellow of the American College of Surgeons; author of a widely known manual on "Operative Surgery"; aged 73; died, November 28.

**Charles Griffin Plummer**, Salt Lake City; Chicago Medical College, 1888; practiced at Salt Lake City since 1891; member of the Utah State Medical Association; for three years colonel in the first infantry of the Utah National Guard; member of the Utah State Commission for Feeble-Minded for four years; on the staff of the Latter-Day Saints Hospital; formerly regent to the University of Utah; awarded testimonial by citizens for service to community and work with youth; in 1935 was awarded twenty-five year veteran silver badge by the National Council, Boy Scouts of America; aged 77; died, November 19.

**Harper M. Workman** © Tracy, Minn.; Chicago Medical College, 1878; member of the House of Delegates of the American Medical Association, 1905-1906; secretary of the Lyon-Lincoln Counties Medical Society; councilor of the third district and past president of the Minnesota State Medical Association; fellow of the American College of Surgeons; first mayor of Tracy; for many years president of the school board; aged 81; died, October 8, of myocarditis and nephritis.

**Eugene Garfield McKeown** © Pipestone, Minn.; University of Minnesota College of Homeopathic Medicine and Surgery, Minneapolis, 1909; fellow of the American College of Surgeons; formerly secretary of the Southwestern Minnesota Medical Society; county health officer; served during the World War; medical director of the Pipestone Indian Hospital; on the staff of the Ashton Memorial Hospital; aged 55; was killed, October 20, in an automobile accident.

**Chester Sylvester Leach** © Brattleboro, Vt.; University of Vermont College of Medicine, Burlington, 1899; past president and secretary of the Windham County Medical Society; vice president of the New England Physical Therapy Society; at one time district health officer; roentgenologist to the Brattleboro Memorial Hospital; aged 60; died, October 23, in the Baker Memorial Hospital, Boston, of coronary embolism.

**Bernard Anthony O'Hara**, Detroit; Washington University School of Medicine, St. Louis, 1917; member of the American Academy of Ophthalmology and Oto-Laryngology; fellow of the American College of Surgeons; served during the World War; at various times on the staffs of the Woman's Hospital, Children Hospital, Henry Ford Hospital and Harper Hospital; aged 47; died, October 29, of rheumatic heart disease.

**Charles Edward Woodbury**, Acworth, N. H.; University of the City of New York Medical Department, 1873; member of the Rhode Island Medical Society; at one time inspector of institutions for lunacy and charity in Massachusetts; formerly superintendent of the Rhode Island Hospital, Providence, and the Foxboro (Mass.) State Hospital; aged 90; died, October 31, at the home of his daughter in Roslindale, Mass.

**John A. Klump**, Williamsport, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1881; past president of the Lycoming County Medical Society; consulting surgeon to the Williamsport Hospital; fellow of the American College of Surgeons; aged 80; died, October 21, in the Danville (Pa.) State Hospital, of cerebral arteriosclerosis and bronchopneumonia.

**Duncan Campbell**, Woodbury, N. J.; Hahnemann Medical College and Hospital of Philadelphia, 1895; member of the Medical Society of New Jersey; for many years lecturer on medical terminology at his alma mater; formerly on the staff of the Underwood Hospital; aged 69; died, October 30, in the Broad Street Hospital, Philadelphia, of cerebral hemorrhage.

**James Garfield Paschen**, Wauwatosa, Wis.; Milwaukee Medical College, 1908; member of the State Medical Society of Wisconsin; associate member in medicine on the staff of Mount Sinai Hospital, Milwaukee; aged 51; died, October 28, in the Columbia Hospital, Milwaukee, of cerebral hemorrhage and splenomyelogenous leukemia.

**David Judson Barton**, Anderson, S. C.; University of Georgia Medical Department, Augusta, 1906; member of the South Carolina Medical Association; president and formerly secretary of the Anderson County Medical Society; at one time on the staff of the Anderson County Hospital; aged 54; died, October 23.

**John Milton Holt**, Los Angeles; Long Island College Hospital, Brooklyn, 1895; served during the World War as director of sanitation for the Houston extracantonment zone; formerly city health officer; for many years attached to the U. S. Public Health Service; aged 63; died, October 15, of coronary occlusion.

**David Clarence Confer**, Duncansville, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1881; member of the Medical Society of the State of Pennsylvania; formerly postmaster, member of the school board and secretary of the board of health; aged 79; died, October 23.

**Frank Clifford Walker**, Windsor, Vt.; Boston University School of Medicine, 1884; for many years health officer of Windsor; at one time city physician in Taunton, Mass.; formerly on the staff of the Morton Hospital, Taunton, Mass.; aged 78; died, October 19, of coronary occlusion.

**Frederick Harvey** © Chicago; Chicago College of Medicine and Surgery, 1915; fellow of the American College of Surgeons; served during the World War; member of the attending staff of the Grant Hospital; aged 46; was killed, December 9, in an automobile accident.

**William James Renwick McFarland**, Syracuse, N. Y.; Baltimore Medical College, 1897; member of the Medical Society of the State of New York; on the staff of the People's Hospital; aged 63; died, October 23, of carcinoma of the pancreas and obstructive jaundice.

**Joseph Benjamin Moxley**, Brantley, Ala.; Georgia College of Eclectic Medicine and Surgery, Atlanta, 1899; member of the Medical Association of the State of Alabama; formerly member of the state legislature; mayor of Brantley; aged 58; died suddenly, October 30.

**John King Stewart**, Tacoma, Wash.; Hahnemann Medical College and Hospital, Chicago, 1910; member of the Washington State Medical Association; served during the World War; aged 68; died, October 21, in the Tacoma General Hospital, of acute coronary thrombosis.

**Edward James Delaney**, Concord, N. H.; Baltimore Medical College, 1903; member of the New Hampshire Medical Society; for many years physician to the state prison; on the staff of the Mary Pillsbury Hospital; aged 58; died, October 21, of cirrhosis of the liver.

**Richard Joseph Shannahan**, Worcester, Mass.; Columbia University College of Physicians and Surgeons, New York, 1903; member of the Massachusetts Medical Society; for many years a police surgeon; aged 57; died, October 31, of arteriosclerotic heart disease.

**Augustus Woodbury Calder**, Providence, R. I.; Harvard University Medical School, Boston, 1895; member of the Rhode Island Medical Society; veteran of the Spanish-American and World wars; aged 67; died, October 25, of coronary occlusion and arteriosclerosis.

**Leo Schram** © Dayton, Ohio; Hahnemann Medical College and Hospital, Chicago, 1892; past president of the Montgomery County Medical Society; city physician; for many years on the staff of the Miami Valley Hospital; aged 68; died, October 5, in Russels Point.

**Antoine A. Laurent** ☉ Minneapolis; Minneapolis College of Physicians and Surgeons, 1911; member of the staffs of St. Mary's, St. Barnabas, Northwestern and Deaconess hospitals; aged 54; died, October 21, of coronary thrombosis and arteriosclerosis.

**James Logan McMillan** ☉ Decaturville, Tenn.; College of Physicians and Surgeons, Memphis, 1907; past president and secretary of the Decatur County Medical Society; aged 51; died, October 31, in the Protestant Hospital, Nashville, of neurofibroma.

**Joseph Foster Grant**, San Diego, Calif.; University of Louisville (Ky.) Medical Department, 1890; fellow of the American College of Surgeons; served during the World War; on the staff of the San Diego County Hospital; aged 67; died, October 27.

**David Lyle**, Rock Hill, S. C.; Medical College of the State of South Carolina, Charleston, 1909; formerly member of the state legislature, and mayor of Rock Hill; on the staff of St. Philip's Mercy Hospital; aged 57; died, October 25, of angina pectoris.

**Herbert Elton Doty**, Concordia, Kan.; Ensworth Medical College, St. Joseph, Mo., 1906; member of the Kansas Medical Society; county coroner; aged 67; on the staff of St. Joseph's Hospital, where he died, October 19, of chronic myocarditis.

**Albert Eugene Fuehs** ☉ Bunker Hill, Ill.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1912; formerly a practitioner in Chicago; aged 61; died, October 27, of diabetes mellitus.

**August Lilienerantz**, Oakland, Calif.; Rush Medical College, Chicago, 1870; member of the California Medical Association; aged 89; died, October 9, in Peralta Hospital, of a skull fracture received when struck by an automobile.

**Fredrick Cushman Kinney**, Hardwick, Vt.; University of Vermont College of Medicine, Burlington, 1882; member of the Vermont State Medical Society; aged 78; died, October 21, in the Hardwick Hospital, of cerebral hemorrhage.

**Mary Frances Deraismes Thornton**, Albany, N. Y.; Cornell University Medical College, New York, 1902; aged 62; died suddenly in October in New York of fracture of the neck of the femur and coronary sclerosis.

**Olav S. Behrentz**, Three Rivers, Mich.; Rush Medical College, Chicago, 1903; for many years a medical missionary in China; aged 63; died, December 8, in the Presbyterian Hospital, Chicago, of coronary sclerosis.

**Arthur Elias Henby**, Seattle; Chicago Homeopathic Medical College, 1897; member of the Washington State Medical Association; served during the World War; aged 62; died, October 8, of coronary disease.

**Howard Leonard Reed**, Henrietta, Texas; University of Oklahoma School of Medicine, Oklahoma City, 1916; served during the World War; aged 52; died, October 23, in a hospital at Wichita, of pneumonia.

**Victor Mackay Daly**, Pontiac, Ill.; University of Edinburgh Faculty of Medicine, Scotland, 1892; served during the World War; on the staff of St. James Hospital; aged 69; died, October 22, of heart disease.

**Nathaniel Hooks Lozier**, Sandersville, Ga.; Atlanta Medical College, 1914; member of the Medical Association of Georgia; aged 46; died, October 21, at a hospital in Atlanta, of a streptococcal infection.

**Jonathan Jay Pitcher**, Mount Pleasant, Iowa; Hahnemann Medical College and Hospital, Chicago, 1906; member of the Iowa State Medical Society; aged 54; died suddenly, October 22, of a cerebral hemorrhage.

**Norman Bates Dresser**, Berlin, N. H.; Medical School of Maine, Portland, 1919; formerly county coroner and city health officer; aged 41; was found dead in bed, October 20, of acute dilatation of the heart.

**George A. Downs**, Spokane, Wash.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1902; served during the World War; aged 59; died, October 18, of disseminated sclerosis.

**William Owen Wisner**, Spokane, Wash.; Medical Department of Omaha University, 1892; formerly county health officer; aged 71; died, October 17, in the Sacred Heart Hospital, of lobar pneumonia.

**Adolph W. Hanson**, Portland, Ore. (licensed in Minnesota by years of practice); (licensed in Iowa in 1898); aged 76; died, October 8, of cardiovascular renal disease and cerebral hemorrhage.

**Edwin Eli Wileox**, Salt Lake City; University of the City of New York Medical Department, 1894; on the staff of the Dr. W. H. Groves Latter-Day Saints Hospital; aged 71; died, October 7.

**Charles Lindley Johnston**, Plattekill, N. Y.; University of Michigan Homeopathic Medical School, Ann Arbor, 1884; aged 78; died, October 24, of paralysis agitans and cardiac dilatation.

**Albert Nicholas Jacob** ☉ Sparta, N. J.; Jefferson Medical College of Philadelphia, 1888; past president of the Sussex County Medical Society; aged 72; died, October 27, of coronary embolism.

**James D. McKie**, Vandale, Ark.; University of Louisville (Ky.) School of Medicine, 1876; member of the Arkansas Medical Society; aged 84; was killed, October 14, when struck by a train.

**George Albert McLane**, Harvard, Ill.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1906; aged 60; died, October 2, of chronic nephritis.

**Charles Augustus Lerch**, Akron, Ohio; Cincinnati College of Medicine and Surgery, 1877; aged 84; died, October 21, in the City Hospital, of hypostatic pneumonia following a Colles fracture.

**Leslie Allen Wilson** ☉ Cameron, Mo.; Northwestern University Medical School, Chicago, 1921; secretary of the Clinton County Medical Society; aged 45; died in October of heart disease.

**George W. Smith**, Washington, D. C.; Howard University College of Medicine, Washington, 1885; aged 81; died, October 8, in the Garfield Hospital, of carcinoma of the bladder.

**Samuel W. Dunlavy**, Coffeyville, Kan.; Keokuk (Iowa) Medical College, College of Physicians and Surgeons, 1902; aged 63; died, October 31, of acute dilatation of the heart.

**William P. Miles Jr.**, New Orleans; University of Maryland School of Medicine, Baltimore, 1890; aged 69; died, October 4, of cerebral thrombosis and arteriosclerosis.

**Frank Segel Smith**, St. Peter, Ill.; Kentucky School of Medicine, Louisville, 1892; county coroner; aged 70; died, October 26, at Vandalia, of heart disease.

**Henry J. Leigh**, Tower City, N. D.; Bennett College of Eclectic Medicine and Surgery, Chicago, 1891; aged 70; died, October 22, of carcinoma of the stomach.

**Paul Lannom Dickson**, Los Angeles; Barnes Medical College, St. Louis, 1900; aged 60; died, October 22, in the Good Samaritan Hospital, of heart disease.

**Gipson W. Stagner**, Richmond, Ky.; Louisville Medical College, 1890; aged 75; died, October 31, in the Good Samaritan Hospital, Lexington, of uremia.

**Thomas A. Lynch**, Brooklyn; Long Island College Hospital, Brooklyn, 1908; served during the World War; aged 51; died, October 28, of heart disease.

**George Logan Hall**, Baltimore; Howard University School of Medicine, Washington, D. C., 1914; aged 51; died, October 31, of aortic insufficiency.

**Albert E. Byron**, Oakland, Calif.; California Eclectic Medical College, Los Angeles, 1895; aged 64; died, October 28, of a self-inflicted bullet wound.

**Henry R. Riemer**, St. Joseph, Mo.; Ensworth Medical College, St. Joseph, 1897; also a minister; aged 90; died, October 29, of arteriosclerosis.

**Gustavus Adolphus Spivey**, Dallas, Texas; University of Louisville (Ky.) Medical Department, 1876; aged 85; died, October 24, of senility.

**Abner Jackson Mynatt**, Lamar, Mo.; University Medical College of Kansas City, 1898; aged 67; died, October 14, of heart disease.

**Edward Wenger**, St. Louis; Beaumont Hospital Medical College, St. Louis, 1890; aged 68; died suddenly, October 17, of heart disease.

**T. I. Mohler**, Palestine, Ark. (licensed in Arkansas in 1903); Civil War veteran; aged 92; died, October 19, of arteriosclerosis.

**John E. Westaver**, St. Louis; St. Louis College of Physicians and Surgeons, 1898; aged 84; died, October 10, of general debility.

**Fred Ernest Zumstein**, Detroit; Miami Medical College, Cincinnati, 1900; aged 70; died, October 30, of cerebral hemorrhage.

## Correspondence

### "AUTOGENOUS SERUM TREATMENT OF NARCOTIC ADDICTION"

To the Editor:—In THE JOURNAL, October 17, page 1337, appeared a lengthy abstract on Autogenous Serum Treatment of Narcotic Addiction (Black, D. M.: *Canad. M. A. J.* 35:177 [Aug.] 1936). I believe that the purpose of Current Medical Literature is to advise readers of advances or new treatments published elsewhere. The following will make clear my object in writing:

According to *La tribune médicale* (December 1929, p. 564) Modinos first called attention to the therapeutic value of serum from blisters some twenty years before this article (1929). Lassablière called attention to this treatment in *Médecine* (December 1928). Modinos reports eight cases of narcotic addiction treated by this method; three of these cases are given in considerable detail.

Based on these reports, I tried this treatment in 1933 in a case of diacetylmorphine addiction. While the cantharides plaster produced an acceptable blister, the restlessness of the patient during the night made him burst the blister. On repetition of the experiment the same unsatisfactory results were obtained. I then considered using his own whole blood. Withdrawal of the 10 cc. was successful, but the blood immediately coagulated in the syringe. Since a foreign protein appeared to be the basis of treatment, I then used 10 cc. of boiled milk intramuscularly with some success. This dose was repeated three times. This case, however, proved to be one of those unmanageable ones, and the patient continued his addiction.

Shortly after I used boiled milk again in a similar case. Four injections, together with phenobarbital by mouth, gave satisfactory results, and the patient had no more desire for narcotics.

In the third case of diacetylmorphine addiction, the patient, treated like the other two, abstained from narcotics for thirty days but then relapsed. Since the drug appears to be well eliminated from the system after such an interval, other reasons for his return to the drug have to be considered.

Lest some one thinks that my treatment is new, I wish to mention Amsler, C.: *Zur Frage der Entwöhnung von narkotischen Giften* (*Klin. Wchschr.* 13:773 [May 26] 1914). He states that Biberfeld used the protein of goat milk parenterally with success. This article came to my attention after the treatment of the three cases mentioned.

HANS SCHROEDER, M.D., San Francisco.

### DETERMINATION OF GALACTOSE IN URINE

To the Editor:—My attention has been called independently by Dr. Walter R. Johnson of Asheville, N. C., and Dr. Hans Wassing of Paterson, N. J., to an error in my article on "Painless Jaundice," which appeared in THE JOURNAL, May 11, 1935, p. 1681. In that article I stated that "the determination of galactose in the urine is done exactly like the quantitative determination for dextrose; the only modification is that, because of the greater reducing power of galactose, it is necessary to multiply the result by 0.7."

Dr. Wassing calls my attention to wide discrepancies in practice in different laboratories and in different textbooks. Thus, he says that Gradwohl in his textbook states that 25 cc. of Benedict's reagent is reduced by 54 mg. of galactose. Therefore, one would use a correction of 1.1. Wassing himself found approximately the same, 55 or 56 mg. of galactose reducing 25 cc. of the reagent.

Mattice in his "Chemical Procedures for Clinical Laboratories," Philadelphia, Lea & Febiger, 1936, page 66, says: "5 ml. of Benedict's quantitative reagent are reduced by 12.5 mg. of galactose." This would correspond to 25 cc. of the reagent being reduced by 62.5 mg. of galactose and would give a correction of 1.25.

I asked Dr. Sobotka, chemist at Mount Sinai Hospital, to investigate this question and his assistant, Miss Miriam Reiner, writes me as follows:

The galactose used in these experiments was *d*-galactose c.p. Pfanstiel with a specific rotation plus 80.5°. This sugar had previously been dried over phosphorus pentoxide in a desiccator. The galactose was carefully weighed and the solution was checked in the polariscope; 2 per cent solution in a 2 cm. tube had a specific rotation of plus 80.5°.

The Benedict reagent was first checked with a glucose solution; 25 cc. was reduced by 50 mg. of glucose. When the galactose solution was used, 65 mg. were necessary to reduce the same amount of Benedict's. Since galactose has a lower reducing value than glucose, the factor is glucose: galactose as 50 mg.: 65 mg., or 1:1.30.

Since the main contaminant of commercial galactose is glucose, the reducing factor of such a sugar would approach the glucose factor, depending upon the amount of glucose present in the sample. The specific rotation of galactose is plus 80.5° and that of glucose is plus 52.5° so that the presence of glucose would lower the specific rotation of the sugar sample.

After taking all these factors into consideration, and comparing my standard galactose with a similar glucose solution, I think we can safely say that the galactose factor for Benedict's quantitative sugar reagent is 1.30.

REUBEN OTTENBERG, M.D., New York.

### WATER FILTRATION VS. CHLORINATION

To the Editor:—My attention has been called to the editorial "Water Filtration vs. Chlorination," which appeared in THE JOURNAL, October 31. The citation of Altona, Germany, as an example of a case in which filtration failed to give adequate public health protection is hardly justified by the reported facts of the classic Hamburg-Altona cholera epidemic of 1892. The Altona experience should properly be cited as a classic example of the public health benefits of filtration and not its limitations. This epidemic preceded both the advent of chlorination for public health purposes and important developments in rapid sand filtration commonly used today.

The outstanding record of water filtration in reducing the typhoid and general death rate in cities where water from polluted sources was formerly used is one of the greatest achievements in public health in America, and much of this was accomplished before chlorination was practiced. It is hardly possible to put chlorination and filtration on the same comparative plane. In modern water works practice the two processes logically go together and in no sense are competitive in meeting modern standards of public health for water supplies. Chlorination is an effective sterilizing agent and its cost in treating public water supplies is almost insignificant in proportion to the benefits derived. Filtration in its broadest sense is a complete process of purifying water including safety, palatability and physical appearance, and the use of chlorine is usually implied when the water is used for domestic purposes.

From a public health standpoint, all public water supplies should be chlorinated. Chlorination, since its first use in water sterilization in 1908, has developed to be one of the greatest factors in safeguarding the public health of cities and communities. But chlorination has its limitations and they must be recognized. Chlorination within practical limits does not destroy certain resistant microscopic organisms found in water, especially *Bacillus welchii* and the cysts of *Endamoeba histolytica*, which are of public health significance. Chlorine or chlorine compounds may result in objectionable tastes in water either through the use of large quantities or as a result of combination with other substances, especially in water pol-

luted by sewage and industrial wastes. It does not remove objectionable tastes and odors such as oil refinery wastes. Chlorine is rapidly absorbed by dissolved and suspended matter in the water, especially by organic compounds.

Not all water supplies, especially ground water, may need filtration, but most surface water supplies regardless of their source can be markedly improved in taste and physical appearance and safety at moderate expense through filtration. Any source of public water supply that is exposed to pollution or objectionable turbidities should be filtered as well as chlorinated. Chicago is a good example. Lake Michigan, the source of supply, is normally clear, but the water at the city's intakes is at times polluted by sewage and industrial wastes and is frequently turbid to an objectionable degree. Chlorination is a public health necessity. Effective chlorination is complicated and difficult in spite of rigid control measures, because of the wide variation in the chlorine demand of the lake water. If this demand were to exceed the chlorine dosage applied to the water, the sterilizing action would be very much limited. A serious health risk exists every time sudden and excessive pollution of the lake waters in the vicinity of the intakes occurs. These periods can be foreseen to some extent but not always, and there is a decided element of risk connected with dependence on chlorination alone. Filtration would correct this condition.

In a filter plant, the time of passage through the settling basins and filters gives the chemist an opportunity not only to sterilize and clarify the water but also to treat it to remove all tastes. This time interval permits adjustment of treatment to correct for sudden changes in the character of the raw water. With intelligent operation a uniformly clear palatable and safe water can be supplied at all times. Filtration permits the maintenance of a clean distribution system and thus clean water through to the tap of the ultimate consumer. Such a condition is not true of chlorinated unfiltered surface waters and frequently of clear ground waters. Raw natural waters of this type frequently cause growths and deposits in mains. Surface waters that may look clear in the glass usually contain large numbers of micro-organisms in suspension. These will settle out in zones of low velocity in a distribution system, decay and cause a fishy, grassy taste in the water and a discoloration that is very objectionable to the consumer.

It is true that many water outbreaks in recent years have been caused by pollution of water en route to the consumer through cross connections with the public distribution system. This is a regrettable condition but one that has nothing to do with the merits of chlorination as against filtration without chlorination, which is doubtful practice. By using the ammonia-chlorine processes for treating the filtered water, residual chlorine can be carried throughout a distribution system without causing objectionable tastes in the water. But this process requires several hours for effective bactericidal action. With a filtration plant this retention period is provided. The cost of complete purification of a public water supply is so low in comparison with the benefits to be derived that the economics of chlorination versus filtration should hardly be considered, especially where the public health is threatened.

ARTHUR E. GORMAN, B.S., Chicago.

*To the Editor:* I have noted with interest the editorial which appeared in the October 31 issue of THE JOURNAL entitled "Water Filtration vs. Chlorination." Owing, however, to the occurrence of a factual error in the reference to the 1892 epidemic of cholera in Altona, Germany, and the consequent reflection on the effectiveness of filters in the purification of water, it is thought that you might wish to present the following comment to your readers.

The cholera epidemic occurring in Germany in 1892 was the first practical demonstration of the effectiveness of filtration in the prevention of water-borne disease. The city of Hamburg, supplied with unfiltered water from the Elbe River, experienced a severe epidemic of cholera, whereas no such epidemic occurred in the neighboring community of Altona, served with the same water after filtration through slow sand filters. Furthermore, the editorial mentioned may be misleading in that it implies that all public water supplies may be effectively chlorinated and that filtration is needed merely to clarify the water and produce a water which is attractive to the consumers.

In general, both chlorination and filtration of water have inherent weaknesses which must be recognized. As a result, both methods of treatment are normally required when polluted surface waters are being treated. This fact may be overlooked, however, and undue confidence placed in the effectiveness of chlorination alone. This justifies a brief statement as to the limitations of chlorination alone, which is inherently subject to interruptions because the failure of chlorine treatment results at once in the delivery of untreated raw water, whereas ineffective filtration is at least partially effective. The effectiveness of chlorination is influenced to a marked extent by the fact that the chlorine dose must be varied under adequate control to compensate for changes in the chlorine demand of the water, which fluctuates with the organic content, temperature and pH value of the water. Furthermore, suspended solids in the raw water, especially those which may protect bacteria associated with pollution, interfere with the disinfecting action and prevent chlorine reaching the embedded bacteria, unless the dose is higher than permissible from the standpoint of the production of a tasteless water. My point is that chlorination must be used in conjunction with filtration when the average surface water is being treated. It is for this specific reason that Milwaukee is now constructing a filtration plant and that a similar plant is being advocated for Chicago.

Fortunately, an approximate quantitative estimate may be made as to the effectiveness of chlorination alone, and of chlorination when combined with rapid sand filtration, as a result of studies by the United States Public Health Service at Cincinnati, Ohio. For instance, these studies indicate quite clearly that the average surface water cannot be effectively chlorinated in the absence of filtration, unless the average number of organisms of the coli-aerogenes group is less than from 80 to about 100 per hundred cubic centimeters of water, provided the number of such organisms in the raw water is less than 450 per hundred cubic centimeters 95 per cent of the time. On the other hand, filtration combined with chlorination permits the effective treatment of a much more heavily polluted water, because with this more complete treatment the average number of organisms of the coli-aerogenes group of the raw water may be from 3,500 to 5,000 per hundred cubic centimeters of water, provided the maximum number of such organisms is less than 20,000 per hundred cubic centimeters 95 per cent of the time.

If the foregoing standards as to the degree of pollution of the raw water are complied with, the treated water will meet the Treasury Department standards as to the quality of water permissible for use on interstate carriers.

I have discussed this matter at considerable length because it is very desirable that the confidence of the public in the effectiveness of filtration plants be maintained and that undue confidence may not be placed in the effectiveness of the chlorination of the average surface water.

PAUL B. BROOKS, M.D., Albany, N. Y.

Deputy Commissioner of Health,  
State of New York.

## Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

### TRAUMA AND ABORTION

*To the Editor:*—A woman, aged 24, whom I had never seen or examined before, had an incomplete abortion of about three and one-half to four months. She gave the history of having fallen from a boat to a stone wharf, a distance of about 3 feet. She states that she fell on her abdomen. I said at the time, and I still feel, that the fall per se did not produce or induce the abortion. But I do not feel that all these cases are caused by distinct pathologic entities, endocervicitis, and so on. Later curettage was done and the secundines were examined microscopically. This case is coming up for trial as the woman is suing the ferry boat company for negligence and stating that the fall is the cause of the abortion. I imagine her lawyers will ask me if a fall could cause an abortion, or, since I never examined the woman before, how could I say anything else than that the fall caused abortion? How long after a fall could it be precluded that the fall was the cause of the abortion? What would you advise as to the position I should take on this matter? Please give reasons. I mean medically and not legally or from a legal standpoint. Would the length of time the patient was pregnant have any bearing on this type of abortion? Have you any figures on this? Please omit name.

M.D., Ohio.

*ANSWER:*—When suits of this type arise, the following points must be determined if possible: (1) the existence of pregnancy prior to the accident, (2) the presence or absence of signs or symptoms of abortion prior to the accident, (3) the presence or absence of factors predisposing to abortion aside from the alleged cause, and (4) the actual occurrence of abortion. Since the correspondent had not examined the patient before the accident he will be unable to testify that she was three or four months pregnant before the accident. He will be unable to vouch for the presence or absence of signs or symptoms of abortion prior to the accident. In considering possible factors in abortion he should try to determine the following: (1) abnormality of the fetus, such as knotted cord, deformity, or other anomaly that could not be the result of trauma to the mother; (2) abnormality of the placenta, such as syphilis or tuberculosis; (3) constitutional factors in the mother predisposing to abortion, such as dietary or vitamin deficiency, or history of previous abortion; (4) existence of focal infections, which are sometimes held responsible for abortion; (5) existence of pelvic abnormalities such as myoma, cysts, cervicitis, severe lacerations, pelvic inflammatory disease and (?) retroversion; (6) systemic diseases, such as syphilis, tuberculosis or toxemia of pregnancy; (7) exposure to toxic agents, such as lead, irradiation, too much alcohol or nicotine; (8) previous operative procedures, such as trachelorrhaphy; (9) intercourse immediately prior to abortion, and (10) vigorous douching with cold or hot water. The possibility of induced abortion prior or subsequent to the accident must be remembered. Since retained secundines were removed and examined microscopically, the physician can testify factually regarding the existence of pregnancy. That is almost the only unqualified statement that he can make. His opinion will be based largely on the presence or absence of the predisposing factors enumerated. For authorities he may consult Taussig (*Abortion, Spontaneous and Induced*, St. Louis, C. V. Mosby Company, 1936, p. 114): "That [external injury or strain] is often an important contributing factor in the initiation of uterine contractions cannot be gainsaid. But in most instances a careful analysis will show other more fundamental causes. One may well be skeptical of the effect of even rather violent external trauma in the production of abortion since we have so many instances in which internal manipulations such as curettage have failed to bring on an abortion." Taussig (p. 114) quotes Seitz that the greatest tendency for traumatic interruption of pregnancy is in the first sixteen weeks, even though at this time the uterus lies more protected in the pelvic cavity than later. Taussig says "Sexual intercourse is probably one of the most positive direct traumatic agents productive of abortion" (p. 114). He considers "psychic trauma" an undoubted factor. D. M. Lindsay (*Trauma and Compensation in Obstetric and Gynecological Cases*, Edinburgh and London, William Hodge & Co., Limited, 1928, pp. 41-42) says "Possibly the proper view to accept [regarding fright, fall or injury] is that accident as a cause of such complication [abortion] is rare in the absence of some already predisposing factor, but that it can cause miscarriage without other predisposing factors I am satisfied." J. R. Miller gives a good list of

references (*Trauma and Compensation in Gynecology and Obstetrics*, *Am. J. Obst. & Gynec.* 26:839 [Dec.] 1933). Presumably a trauma severe enough to cause abortion would promptly produce abortion. No time limit can be stated because of the possibility of missed abortion with a long latent period. The physician in the present case will do well to confine himself to facts and state his own opinion cautiously.

### PERSISTENT YAWNING

*To the Editor:*—I have a case of hysteria manifested by continuous yawning, which began about five months ago following recovery from a successful operation for removal of the gallbladder. The yawning becomes so severe at times that the jaws become painfully sore. Sedatives give only temporary relief. Endocrine therapy has not seemed to help any. I am unable to find any foci of infection. I would appreciate any suggestions you may offer.

M.D., Louisiana.

*ANSWER:*—In normal persons and other animals, yawning is essentially an involuntary deep inspiration accompanied by wide opening of the mouth and frequently stretching of the body musculature. The conditions leading to this act are usually marked mental and physical weariness or fatigue, such as may be brought on by prolonged mental or physical exertion, low blood pressure or some degree of tissue asphyxia. The performance of this act in one individual has a peculiar suggestive potency in others, leading to the same act in them, if conditions are favorable. Persistent yawning in hysteria is usually only one (and not a frequent) manifestation of hysteria. There is no known reason why hysterical yawning should be connected with convalescence from a gallbladder operation, unless the operation resulted in prolonged low blood pressure or interference with the respiration leading to tissue asphyxia, in which case, in a susceptible person, the yawning may have been established as a habit; but this would scarcely be called true hysteria. Endocrine therapy in this condition would be purely empirical and sedatives, of course, of only temporary value. If the patient is more or less depressed, thyroid therapy might help a little. If there is interference in circulation or respiration, stimulants should act more favorably than sedatives. If it is a habit developed during a long period of convalescence, stimulants and cheerful and interesting surroundings might help to overcome the habit. If it is true hysteria and the person manifests other indications, such as chronic fatigue and depression, one should try vasomotor and central nervous system stimulants and a cheerful and stimulating environment, combined with the usual psychomotor reeducation therapy, sometimes effective in hysteria.

### INVERTED VISION

*To the Editor:*—A boy who will be 9 years old next January and is now in the third grade is a very good student—about B or B plus. Within the last three weeks he has taken to turning his book upside down to read. He also inverts his number book. He reads from the blackboard and only seldom tells the teacher that she is writing upside down. He reads numbers from the blackboard and usually gets the work done right side up on paper. Only once has he written his name upside down. He plays an instrument and tells his mother that he doesn't see how she can play music upside down. He was reading a book. I asked him what the story was about and I took the book and looked at it and handed the book back to him right side up. He said he couldn't read the book upside down and proceeded to invert it and read. I do not think a youngster of that age would think of this as a means of gaining attention and be so consistent in it.

M.D., Louisiana.

*ANSWER:*—Cases of reversals and inversions in reading are not uncommonly found in a large school system; in fact, their occurrence is sufficiently frequent so that considerable work has been done by educational psychologists with reference to this problem. There are several theories as to its causation, the most prominent of which has to do with cerebral dominance. Some observers seem to think that inversions or reversals occur in left handed individuals who are compelled to use the right hand or vice versa. Others who distinguish the problem of "eyedness" from "handedness" seem to think that, although the individual may be using the proper hand, contralateral eye dominance may be present, which adds to the confusion. After an emotional upset or an acute ailment a suppressed eye or hand dominance may cause a sudden change in the capacity to read or to see right side up or from right to left. Some have shown that improper teaching methods are extremely important. Again, lack of fusion in which the retinal image of one eye is confused with the other because of muscle impairment or some other ocular defect may be significant. Bad home or school conditions, both patent and latent, may lie behind the emotional upset, which in turn may not be readily apparent to the inexperienced examiner.

A diagnosis of this condition and an analysis of its cause would have to be made on the basis of careful ophthalmic and physical examination, an analysis of the history by a psychiatrist who is skilled in dealing with reading disabilities and who is familiar with child behavior disturbances, in addition to a psychologic study by a psychologist who is a specialist in "corrective reading." The treatment usually is a matter of reeducation after any obvious cause has been removed, and this reeducation brings into account the use of kinesthesia both of the tongue and of the general body musculature. Home trial and error methods of correction are not only contraindicated but may actually cause emotional and other disturbances which may be worse than the immediate disorder, but it must not be forgotten that a condition of this sort may correct itself, although this is not usually the case. This means that it is better to neglect the problem than to "tinker." It must be remembered that this type of condition can occur in children of 9 or even younger as an attention-gaining mechanism and that it often requires a careful analysis of the emotional milieu of the child to see what the situation is that lies behind it. It would be advisable for the physician, if he has time, to check over some of the references in Marion Monroe's book "Children Who Cannot Read" dealing with this problem. Perhaps there is a large school system not too distant where there is a reading specialist who can give immediate advice.

#### SENSITIVITY TO BLOOD AND SERUM

*To the Editor:*—As an intern in 1931 I observed in the dispensary that occasionally I would develop a more or less severe localized skin reaction, with redness, itching and burning, to the blood of certain patients. The reaction did not occur always even though in some cases the blood was allowed to remain for some time; in other cases, itching would call my attention almost at once to blood stains, usually on the inner surface of the arm. I was interested in the phenomenon and thought that I might at some time investigate it thoroughly. My attention has again been called to this idea of allergic reaction by two rather recent cases of atypical reaction following blood transfusions. One occurred in a tuberculous patient, almost immediately after transfusion, as an acute pulmonary edema; the other happened not long afterward to another patient with traumatic hemothorax as a fairly typical asthma, several hours after blood transfusion, and responded to atropine sulfate (ephedrine was not given for fear of raising the blood pressure). Can you tell me whether anything has been done in the line of skin sensitivity to blood? It seems that there are other incompatibilities besides that disclosed by blood grouping and cross agglutination. I have talked with several pathologists and they said that the idea was entirely new to them.

MARGARET F. BENJAMIN, M.D., Muncie, Ind.

*ANSWER.*—Positive skin reactions to human blood serum with a positive complement fixation reaction was reported by György and Witebsky (*München. med. Wchnschr.* 50:599, 1924) in one case. The two specimens of blood were of the same group. One blood transfusion caused no trouble. The second blood transfusion, twenty days later, was followed by a severe anaphylactic reaction, which however, was not fatal. The authors believe that the child was sensitive to some substance present in the serum itself or to some food present in the serum to which the child was sensitive. It is barely possible that the inquirer may be highly skin sensitive, without necessarily having clinical symptoms, to certain foods that may be present at various times in sufficient concentration in the serums with which she has come in contact to produce skin reactions. This assumption is highly speculative, as there is great dilution of such foods by the blood serum.

Regarding the second part of the inquiry, it is not stated whether the donors were merely typed or whether compatibility tests were done in addition. Occasional reactions may occur when universal donors (group O) have a very high titer of agglutinins or hemolysins in their serum, so that dilution by the recipient's blood is insufficient. A similar reaction may occur in universal recipients (group AB) when the donor's serum may be unusually high in agglutinins of hemolysins, so that dilution in the recipient's blood is insufficient.

In addition, one must consider the possibility of the presence in the donor's blood of "extra agglutinin 1." This was discovered in occasional bloods of groups O, A and B by Landsteiner and Levine. It is demonstrable when compatibility tests are done at temperatures of from 25 to 30 C. They may not be detected when tests are done at room temperature. Fortunately, reactions do not occur at a temperature above 30 C. The subject of anomalous agglutinins is however still under investigation, and occasional reactions occur which are not explainable by our present knowledge.

Reactions of an allergic nature may occur if the donor, previous to the transfusion, has ingested some foods to which the recipient is sensitive (Duke and Stoffer: *M. Clin. North America* 7:1523, 1924). In addition, it may be possible to

induce a state of passive sensitization by transfusing the blood of an allergic individual. The recipient may develop a reaction in the presence of the antigen. If, for instance, the blood of a cottonseed sensitive patient is used, the recipient may in a few hours develop symptoms from contact with a cotton filled mattress.

Reactions may also be due to citrated blood, to foreign matter present in the transfusion apparatus, either in the glass connections or in the rubber tubing, or to incipient coagulative changes in the blood as it passes through the apparatus (Satterlee, H. S., and Hooker, R. S.: Transfusion of Blood with Special Reference to the Use of Anticoagulants, *THE JOURNAL*, Feb. 26, 1916, p. 618).

#### DOSAGE OF BROWN MIXTURE FOR COLD

*To the Editor:*—Will you kindly send me a prescription of brown mixture for cold for an adult and state how often it must be taken? Also a prescription of brown mixture for children from 2 to 4 years old and how they must take it, as I am interested in a good formula of brown mixture.

THOMAS GAERSTE, M.D., Curaçao, Dutch West Indies.

*ANSWER.*—The formula for brown mixture or the compound mixture of opium and glycyrrhiza is to be found in the U. S. P. XI. Its composition is as follows:

Fluidextract of glycyrrhiza.....	120	cc.
Antimony and potassium tartrate.....	0.24	cc.
Camphorated tincture of opium.....	120	cc.
Spirit of ethyl nitrite.....	30	cc.
Glycerin.....	120	cc.
Distilled water.....	a sufficient quantity to make	1,000 cc.

While the dose of this mixture for an adult is a teaspoonful every two to four hours, one may give a child one or two drops of it for each year of age every two hours.

It should be understood, however, that it is not a cure for a cold in any sense of the word. It may, if taken with an abundance of fluid, tend to improve the secretion of the affected mucous membrane. It may lessen the violence of coughing; but, as colds are infections, the patient's system must acquire immunity. Toward immunization this medicine contributes nothing.

#### USE OF CAMPHOR IN OIL TO SUPPRESS LACTATION

*To the Editor:*—A white woman, aged 26, single, had a criminal abortion two years ago. The menstrual history is normal. Ever since the abortion the patient has observed a milky, watery discharge from the breasts, which is quite profuse at times. The breasts are not painful, or enlarged. The Wassermann reaction is negative. Physical and pelvic examinations are negative. Can you give me any suggestions as to the treatment for this condition? Please omit name. M.D., New York.

*ANSWER.*—Camphor in oil administered intramuscularly has a definite inhibiting effect on lactation. This effect appears to be due to a direct action of the drug on the secretory epithelium of the breasts. For the suppression of milk either immediately after the birth of a stillborn child or later when a child is weaned, L. G. McNeile (*West. J. Surg.* 43:61 [Feb.] 1935) recommends that on the first day two 1½ grain (0.1 Gm.) doses of camphor in oil be injected intramuscularly, one in the morning and the other at night. On the second, third and fourth days one hypodermic of the same amount is given in the morning. If the breasts show any evidence of active function after the fourth day, an injection is given on the fifth and sixth days also. Since there is no harm in administering this form of therapy, it should be tried in the present case.

#### AGE OF LOSS OF POTENCY—MENOPAUSE

*To the Editor:*—1. What is the average age of beginning loss of libido or beginning impotence in males, without venereal history? 2. What is the average age at which women are considered past the childbearing age?

M.D., New York.

*ANSWER.*—1. Normally the absence of libido and impotence should coincide, but this is by no means always the case. The trouble is when the libido continues but the power for counction is lost. In both conditions the onset is gradual and may be said to start at the age of 65. This age is the average age, but it is nothing unusual for men to be sexually active at 70, 80 or even later. Pathologically of course, even in the absence of any venereal disease, conditions may appear at early ages.

2. As a rule to which there are exceptions, women do not become pregnant after the menopause. Statistics from those who have investigated this point in hundreds of cases seem to indicate that in the United States the menopause comes on at the age of 50. Different countries and different races vary greatly in this regard.

## ARTIFICIAL FEEDING OF INFANTS

*To the Editor:*—Is it the common practice of pediatricians in the United States to arrange the formula of bottled-fed infants so that they are given whole (cow's) milk at 5 months of age? I am assuming in this question that the infant must be put on the bottle from birth.

LEON PARIS, M.D., Bronx, New York.

**ANSWER.**—A normal, full term, bottle fed infant requires from 1½ to a maximum of 2 ounces of cow's milk per pound of body weight in twenty-four hours and a total fluid requirement of 3 ounces per pound of body weight. This means that the average 5 months old infant will receive from 24 to 30 ounces of cow's milk in twenty-four hours. The usual infant of this age will take five bottles of 7 ounces each, or a total of 35 ounces, which necessitates the adding of from 11 to 5 ounces of boiled water to the milk. Whole cow's milk is ordinarily not prescribed before the latter part of the first year, as gastric and intestinal digestion are usually not adequate for undiluted milk before this time.

## URTICARIA

*To the Editor:*—A patient has severe urticaria and I have had no success whatever with the many known prescriptions. Suffice it to say that I have tried all therapy that is listed in the attempt to abort such a condition. I shall be grateful if you will suggest or furnish me any data that you have at your disposal. In addition, I shall be grateful for any intravenous or intramuscular medication that may be attempted in just such an affliction. I am most anxious to abort this condition. I may add that the patient has been previously diagnosed by another man as having petit mal and is a daily user of one tablet of phenobarbital. Does the latter bear any relation to the urticaria? If so, would it be advisable to substitute elixir of phenobarbital?

BENEDICT B. BACKLEY, M.D., Jacksonville, Ohio.

**ANSWER.**—Phenobarbital may be suspected as a possible cause of the urticaria. A patch test with phenobarbital might give some information as to its status in producing the eruption. If it is responsible for the dermatosis, the elixir of phenobarbital will produce the same effect. Intramuscular injections of epinephrine solution and intravenous injections of calcium gluconate solution or of the patient's own blood are worth trying.

## TREATMENT OF EPIDIDYMITIS

*To the Editor:*—A man with acute gonorrhea has had prostatitis and unilateral epididymitis. His symptoms have improved until there is only slight tenderness in the epididymis and in the prostate. A moderate discharge is still present. How soon will it be safe to attempt the passing of sounds? How often should the prostate and seminal vesicles be massaged? Please omit name.

M.D., Iowa.

**ANSWER.**—Unless the patient has a stricture there is little reason for passing sounds in this case. Routine massage of the prostate and vesicles, followed by an instillation of a mild silver nitrate solution, should not be started until about two weeks after the swelling in the epididymis and acute symptoms have subsided. This massage should not be vigorous at first and should be carried out at intervals of from five days to one week.

## TREATMENT OF PITYRIASIS ROSEA

*To the Editor:*—What is the present accepted treatment for pityriasis rosea? Is ultraviolet radiation of any value in this condition? Please omit name.

M.D., Iowa.

**ANSWER.**—Pityriasis rosea is a self-limited disease, but in the majority of instances its course can be definitely shortened by the use of mild erythema exposures of ultraviolet rays at intervals of from five to seven days, plus soothing local treatment. The latter may consist of applications of calamine lotion, calamine liniment or boric acid ointment, or 5 per cent boric acid in rose water ointment. For scaling lesions, from 2 to 3 per cent salicylic acid may be added to the ointments.

## EFFECTS OF MYDRIATICS

*To the Editor:*—An optometrist in this city is claiming that permanent blindness was caused in a case in which "drops" were used in the eyes, presumably homatropine or atropine 1 per cent. Is this possible? Please omit name.

M.D., North Carolina.

**ANSWER.**—Permanent blindness can follow the use of a mydriatic only in case glaucoma was present at the time of administration or some form of glaucoma resulted from the drops and did not receive or respond to adequate treatment. There are no recorded instances of blindness due to the use of a mydriatic without the intervention of increased intra-ocular pressure.

- DELAWARE:** Dover, July 13-15. Sec., Medical Council of Delaware, Dr. Joseph S. McDaniel, Dover.
- DISTRICT OF COLUMBIA:** Washington, Jan. 11-12. Sec., Commission on Licensure, Dr. George C. Ruhland, 203 District Bldg., Washington.
- IDaho:** Boise, April 6. Commissioner of Law Enforcement, Hon. Emmett Frost, 205 State House, Boise.
- ILLINOIS:** Chicago, Jan. 26-28. Superintendent of Registration, Department of Registration and Education, Mr. Homer J. Byrd, Springfield.
- INDIANA:** Indianapolis, June 22-24. Sec., Board of Medical Registration and Examination, Dr. William R. Davidson, 301 State House, Indianapolis.
- IOWA:** *Basic Science.* Des Moines, Jan. 12. Sec., Prof. Edward A. Benbrook, Iowa State College, Ames.
- MAINE:** Portland, March 9-10. Sec., Board of Registration of Medicine, Dr. Adam P. Leighton, 192 State St., Portland.
- MICHIGAN:** Ann Arbor and Detroit, June 9-11. Sec., Board of Registration in Medicine, Dr. J. Earl McIntyre, 202-3-4 Hollister Bldg., Lansing.
- MINNESOTA:** *Basic Science.* Minneapolis, Jan. 5-6. Sec., Dr. J. Charnley McKinley, 126 Millard Hall, University of Minnesota, Minneapolis. *Medical.* Minneapolis, Jan. 19-21. Sec., Dr. Julian F. Du Bois, 350 St. Peter St., St. Paul.
- MONTANA:** Helena, April 6. Sec., Dr. S. A. Cooney, 7 W. 6th Ave., Helena.
- NEBRASKA:** *Basic Science.* Omaha, Jan. 12-13. Director, Bureau of Examining Boards, Mrs. Clark Perkins, State House, Lincoln.
- NEVADA:** *Reciprocity.* Carson City, Feb. 1. Sec., Dr. John E. Worden, Carson City.
- NEW HAMPSHIRE:** Concord, March 11-12. Sec., Board of Registration in Medicine, Dr. Charles Duncan, State House, Concord.
- NEW JERSEY:** Trenton, June 15-16. Sec., Dr. James J. McGuire, 28 W. State St., Trenton.
- NEW MEXICO:** Santa Fe, April 12-13. Sec., Dr. Le Grand Ward, Box 693, Santa Fe.
- NEW YORK:** Albany, Buffalo, New York and Syracuse, Jan. 25-28. Chief, Professional Examinations Bureau, Mr. Herbert J. Hamilton, 315 Education Bldg., Albany.
- NORTH DAKOTA:** Grand Forks, Jan. 5-8. Sec., Dr. G. M. Williamson, 4½ S. 3rd St., Grand Forks.
- OREGON:** Portland, Jan. 5-7. Sec., Dr. Joseph F. Wood, 509 Selling Bldg., Portland.
- PENNSYLVANIA:** Philadelphia, Jan. 5-9. Sec., Board of Medical Education and Licensure, Mr. James A. Newpher, Education Bldg., Harrisburg.
- PUERTO RICO:** San Juan, March 2. Sec., Dr. O. Costa Mandry, Box 536, San Juan.
- RHODE ISLAND:** Providence, Jan. 7-8. Chief, Division of Examiners, Mr. Robert D. Wholey, 366 State Office Bldg., Providence.
- SOUTH DAKOTA:** Pierre, Jan. 19-20. Dir., Division of Medical Licensure, Dr. B. A. Dyar, Pierre.
- VERMONT:** Burlington, Feb. 10-12. Sec., Board of Medical Registration, Dr. W. Scott Nay, Underhill.
- WASHINGTON:** *Basic Science.* Seattle, Jan. 7-8. *Medical.* Seattle, Jan. 11-13. Dir., Department of Licenses, Mr. Harry C. Huse, Olympia.
- WEST VIRGINIA:** Charleston, March 1. Sec., Public Health Council, Dr. Arthur E. McClue, State Capitol, Charleston.
- WISCONSIN:** Madison, Jan. 12-14. Sec., Dr. Henry J. Gramling, 2203 S. Layton Blvd., Milwaukee.
- WYOMING:** Cheyenne, Feb. 1. Sec., Dr. G. M. Anderson, Capitol Bldg., Cheyenne.

## NATIONAL BOARD OF MEDICAL EXAMINERS

**NATIONAL BOARD OF MEDICAL EXAMINERS:** *Parts I and II.* Feb. 9-11, May 10-12, June 21-23, and Sept. 13-15. *Part III.* New York, Jan. 11-13 and Chicago, Jan. 19-21. Ex. Sec., Mr. Everett S. Elwood, 225 S. 15th St., Philadelphia.

## SPECIAL BOARDS

**AMERICAN BOARD OF DERMATOLOGY AND SYPHILOLOGY:** *Written examination for Group B applicants* will be held in various cities throughout the country, April 17. *Oral examinations for Group A and B applicants* will be given in Philadelphia, June 7-8. Sec., Dr. C. Guy Lane, 416 Marlborough St., Boston.

**AMERICAN BOARD OF INTERNAL MEDICINE:** *Written examination* will be held simultaneously in different centers of the United States and Canada in March. *Practical examination* will be given in St. Louis in April and at Philadelphia in June. Chairman, Dr. Walter L. Bierring, 406 Sixth Ave., Rm. 1210, Des Moines.

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY: *Written examination for Group B applicants* will be held in various cities throughout the United States and Canada, March 6. *Practical, oral and clinical examinations for Group A and B applicants* will be held at Atlantic City, N. J., June 7-8. *Applications must be received at least sixty days prior to the examination dates.* Sec., Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh (6).

AMERICAN BOARD OF OPHTHALMOLOGY: Los Angeles, Jan. 23. Sec., Dr. John Green, 3720 Washington Blvd., St. Louis, Mo.  
AMERICAN BOARD OF ORTHOPAEDIC SURGERY: Cleveland, Jan. 9. Sec., Dr. Fremont A. Chandler, 180 N. Michigan Ave., Chicago.  
AMERICAN BOARD OF OTOLARYNGOLOGY: Philadelphia, June 7-8. Sec., Dr. W. P. Wherry, 1500 Medical Arts Bldg., Omaha.  
AMERICAN BOARD OF PATHOLOGY: Chicago, March 26-27. Sec., Dr. F. W. Hartman, Henry Ford Hospital, Detroit, Michigan.  
AMERICAN BOARD OF PEDIATRICS: New York, Jan. 23. Sec., Dr. C. A. Aldrich, 723 Elm St., Winnetka, Illinois.  
AMERICAN BOARD OF PSYCHIATRY AND NEUROLOGY: New York, Dec. 29-30. Sec., Dr. Walter Freeman, 1028 Connecticut Ave., Washington, D. C.  
AMERICAN BOARD OF RADIOLOGY: Atlantic City, June 4-6. Sec., Dr. Byrl R. Kirklin, Mayo Clinic, Rochester.

### Wisconsin June-July Report

Dr. Robert E. Flynn, former secretary, Wisconsin State Board of Medical Examiners, reports the written and practical examination held in Milwaukee, June 30-July 3. The examination covered 19 subjects and included 100 questions. An average of 75 per cent was required to pass. Ninety candidates were examined, 89 of whom passed and 1 failed. Thirty-one physicians were licensed by reciprocity. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
College of Me	82	(1935)	82
Loyola Univer	81	(1932)	81

### Book Notices

**A Text-Book of Neuro-Anatomy.** By Albert Kuntz, Ph.D., M.D., Professor of Micro-Anatomy in St. Louis University School of Medicine. Second edition. Cloth. Price, \$6. Pp. 519, with 307 illustrations. Philadelphia: Lea & Febiger, 1936.

This work has been thoroughly revised. The anatomic details are correlated with the fundamental structural plan of the vertebrate nervous system. The anatomic structure of the parts of the human nervous system are discussed in the light of the present knowledge of phylogenic, anatomic and physiologic relationships. There are twenty-six chapters, starting with evolution and comparative anatomy of the nervous system and concluding with a brief laboratory outline. Embryology, topography, histology, anatomy and physiology of the entire cerebrospinal, peripheral and autonomic nervous systems are clearly discussed and interpreted. The autonomic nervous system included in this book comprises material from the first five chapters of the author's book on the autonomic nervous system. The discussion of the cerebral hemispheres is brilliant because of its extreme comprehensiveness and clarity, and the ability to make interesting reading. In fact, the entire book is written in a concise and clear cut maner, thus making it a desirable textbook for students as well as for medical men interested in neurology. It is highly recommended.

**Osnovy morfologii nervnoy sistemy v normalnom i patologicheskom sostoyaniyakh.** Tom I: Obshchaya normalnaya i patologicheskaya gistologiya; gilya i mezoderma. [By] L. I. Smirnov. [Morphology of Nervous System in Normal and Pathologic Conditions. Volume I: General Normal and Pathologic Histology; Glna and Mesoderm.] Boards. Price, 18 rubles. Pp. 360, with 238 illustrations. Kharkov: Gosmedizdat U. S. S. R., 1935.

In a short preface the author states that in the Soviet Republics the interest in neuropathology has become of late so great that there is hardly a neuropsychiatric establishment without a properly equipped histopathologic laboratory. Psychiatric institutes are being gradually equipped with necropsy rooms, and the growing number of research neuropsychiatric centers attracts numerous young physicians eager to work in the field of pathology. In the introduction (thirty-six large pages of small print) the author enlarges on the importance of neuropathology in general, without the knowledge of which, he justly states, there can be no progress in the intelligent understanding of neuropsychiatric problems. Unfortunately, he did not spare efforts to exaggerate the shortcomings of neuropathology or to enlarge on the difficulties associated with its studies, such as the necessity of extensive clinical observations and of a previous training in anatomy, physiology, histology, embryology and other allied sciences. The picture painted by the author is so bewildering that the young men to help whom the book has been written may become discouraged from taking up the study of neuropathology. Even more discouraging is the mode of presenting the subject. Thus, while the book contains an immense amount of valuable information, the arrangement of the material is loose and therefore confusing. Discussing glia, for instance, the author is not satisfied with a detailed general description of the various forms of glial elements and the methods of their study but does not hesitate to take up in detail the numerous morbid conditions (including gliomas) in which abnormal glia is encountered. It would be better to refer to the special volume and thus avoid repetitions, which are numerous. The author thinks it equally important to describe the condition of the glia found in an old dog or to discuss in four pages the minute types of granules occurring in glia. Even such topics as the nature and origin of rod cells do not require seven pages (including four pictures). On the

other hand, such an important subject as that of secondary nerve degeneration is given about half a page. The reading is rendered more difficult because of frequent quotations from the German and occasionally Russian medical literature. German quotations are so numerous that the impression is gained that one is reading the verbose contributions of Spielmeyer and Jakob, which are quoted with especial frequency. Non-German authors are mentioned only when their publications happened to appear in German, though the author gives the English caption of Cushing and Bailey's book on classification of gliomas (but this also appeared in a German translation). The book may be looked on as a review of or a compilation from German and Russian writings on various topics of neuropathology and for this reason may be of some help as a reference book. The illustrations, though numerous, are for the most part worthless because of the poor quality of the paper.

Annual Reprint of the Reports of the Council on Pharmacy and Chemistry of the American Medical Association for 1935, with the Comments that Have Appeared in The Journal. Cloth. Price, \$1. Pp. 139. Chicago: American Medical Association, 1935.

The contents of the 1935 volume of collected reports of the Council fall roughly into three classifications: preliminary and special reports, reports on the omission of products from New and Nonofficial Remedies, and reports on products held non-acceptable for N. N. R. The medicinal products concerned thus fall respectively into the following groups: products which have been considered and found promising but not as yet fully acceptable, products which have been accepted but have not continued to meet the standards of acceptability, and products which on initial or continued consideration have been found definitely unacceptable. It is understood, of course, that the term "acceptable" implies that the product has sufficient value or promise of value to be used by the general medical profession and further that it is marketed in accordance with the Council's rules.

The Council's preliminary reports cover the first line of therapeutic advance. In general these reports give a review of the evidence for products representing the latest therapeutic investigation and indicate the procedure and requirements necessary for their ultimate admission to the physician's armamentarium. In this volume the report on progynon-B touches on the active and promising field of ovarian hormone therapy and the report on vitamin A and urinary lithiasis sets up a warning sign in the chaotic no man's land of overenthusiastic claims for vitamin therapy. An additional pronouncement in this field is found in the report on shotgun vitamin therapy. The Council is indeed to be commended for its rational stand in its attempt to clear up the mists of pseudoscience that have invaded this field.

The reports on articles omitted from New and Nonofficial Remedies usually give a parting notice to products on the way to the therapeutic scrap heap. The reports on lithium salts and tyramine hydrochloride are excellent examples of this type. The report on rossium, on a bacillus acidophilus culture and on dinitrophenol should also be noted as dealing with products that have been tried and found wanting.

It is significant that reports on products which on first examination are found flagrantly unacceptable comprise less and less of the bulk of the Council's work. They are represented in this volume by such reports as that on Elixir Aurine, an apparently uncontrolled mixture of gold tribromide and ephedrine for use in the treatment of whooping cough; Ho-Mo-Sol, a solution of sodium hypochlorite and sodium carbonate representing an unessential modification of a standard hypochlorite solution, marketed under a noninformative proprietary name and promoted to the public; the Imbak products, which are apparently bacterial preparations of undeclared composition, marketed with absurdly comprehensive claims, and Sulfoin, an ointment of solution of sulfuretted lime marketed under a proprietary name with inadequately supported therapeutic claims.

One is tempted to mention each one of the valuable reports included in this volume, but the limits of a review must be observed. Attention must, however, be called to the reports on omission from New and Nonofficial Remedies of Caprokol and Hexylresorcinol Solution S. T. 37 as illustrative of the judicial fairness and careful procedure of the Council on Pharmacy and Chemistry of the American Medical Association.

Les kystes hydatiques de la rate. Par L. Sabadini, chirurgien des hôpitaux d'Alger. Préface du Professeur Costantin. Paper. Price, 32 francs. Pp. 200, with 82 illustrations. Paris: Masson & Cie, 1936.

Sabadini's monograph on hydatid cysts of the spleen lives up to the tradition of the French school and the publishing house of Masson & Cie. In a clear and analytic manner the author goes into the greatest detail in his discussion of a lesion that is rare even in hydatid disease and seen only in regions where the *echinococcus* is endemic. In fact, Sabadini introduced his discussion of the subject by saying that only about 2 to 4 per cent of hydatid cysts become localized in the spleen. It is rarely reported from Iceland and Australia, being more commonly seen in Algiers and Italy. The chapters are on incidence, history, pathogenesis, pathology, symptomatology and signs, diagnosis and treatment. References are numerous throughout the monograph and it closes with a complete bibliography listing 288 articles and making the monograph desirable for this reason alone. The most valuable chapter by far is the one on treatment, which is subdivided under the headings of indications and operative procedures. The author clearly and logically brings out the complicating factors of enormous size, dangers of anaphylaxis, massive adhesions, dangers of spreading the parasites into the peritoneum and secondary infection, which have to be considered in the individual case in choosing marsupialization, removal of the cyst with primary closure or splenectomy. The indications and contraindications with the detailed technic are given clearly and succinctly. Coming from a surgeon of wide experience in Algerian hospitals, this chapter is noteworthy and adds an individual and personal note to the monograph with its complete bibliography.

A Diabetic Manual for Practitioners and Patients. By Edward L. Boritz, A.B., M.D., F.A.C.P., Associate Professor of Medicine, Graduate School of Medicine, University of Pennsylvania. With a foreword by George Morris Piersol, B.S., M.D., F.A.C.P., Professor of Medicine, Graduate School of Medicine, University of Pennsylvania. Fabrikoid. Price, \$2. Pp. 222, with 12 illustrations. Philadelphia: F. A. Davis Company, 1936.

This little volume is intended both for the practitioner and for the patient, a combination that is always difficult to manage. It is bound to become too technical for the patient. Such a book, of which this is an example, contains too many technical terms that are foreign to a layman in spite of the glossary of medical terms at the beginning of the book. It contains too much that is neither of interest nor of use to the patient and tends to confuse him rather than to clarify the problem for him. From the standpoint of the patient therefore it is top heavy. From the standpoint of the practitioner, it is an excellent little volume, full of practical type of information. Any one in busy practice will find a good guide here in the treatment, diagnosis and complications of diabetes. In the chapter on diet the author has used a new and simple method of measuring in place of the usual weighing of the food, which is a practical and helpful method as it simplifies the routine and is adequate for all practical purposes. The chapter on food analysis and recipes follows much the usual lines and to this are added lists of the composition of alcoholic beverages, a helpful feature for reference.

An Introduction to Surgery. By Rutherford Morison, M.D., F.R.C.S., M.A., and Charles F. M. Saint, C.B.E., M.D., M.S., Professor of Surgery, Cape Town University, South Africa. Third edition. Cloth. Price, \$5. Pp. 367, with 231 illustrations. Baltimore: William Wood & Company, 1935.

This rather small volume is devoted to the establishment of general principles as applied to the teaching of surgery. The authors point out that deviations from normal health are due to changes in the body caused by external or internal stimuli, which may be divided into two main groups: noninfective—mechanical, thermal, chemical, electrical, x-ray—and infective. A proper understanding of surgery consists in an understanding of how these harmful stimuli or irritants affect the body and how nature overcomes these changes. These facts constitute the general principles and the authors in this textbook are concerned with the presentation of these principles and their constant, forceful repetition and illustration by cases. The volume is not a complete textbook of surgery. The subjects taken up include shock, hemorrhage, infection, inflammation, wounds, inflammatory fever, effects of interference with blood supply

of tissues, suppuration, specific infectious diseases, ulcers, gangrene, syphilis, tuberculosis, malignant disease, the hollow muscular systems, the serous cavities, natural cures and indications for operation. It ends with a chapter on pathologic conditions illustrating the principles of surgery: consideration of etiology, pathology, symptomatology, diagnosis and treatment. The work contains nothing that is essentially new and it could not be used as a textbook on general surgery, it is so incomplete; but it must have been found of value to warrant its third edition. The authors are men of large experience and high standing, and their manner of presenting surgical principles is interesting and valuable. Their aim and their achievements are to aid the student in thinking out for himself the problems presented to him clinically and in textbooks, placing each problem in a general group rather than considering it as an isolated entity. Once the student has gained such a point of view, he ceases to be overwhelmed by the mass facts presented to him, thinks systematically and logically, and finds greater interest in the subjects.

**The Therapeutic Agents of the Pyrrole and Pyridine Group Including the Tropolol, Scopoline, Egonine, and Granatoline Derivatives. The Relation Between Their Chemical Constitution and Pharmacologic Action.** By W. F. von Oettingen, M.D., Ph.D., Director of the Haskell Laboratory of Industrial Toxicology, Wilmington, Delaware. Cloth. Price, \$4.75. Pp. 258. Ann Arbor, Michigan: Edwards Brothers, Inc., 1936.

This volume is a real contribution to scientific literature because it represents a collection of chemical and pharmacologic data on several series of nitrogen-containing organic compounds. The subtitle on the fly leaf indicates that the volume discusses "The Relation Between Their Chemical Constitution and Pharmacologic Action." Unfortunately, this is not the case. In the last paragraph the author indicates that he recognizes no such relationship, but he suggests that the relationship may be established when a greater fund of knowledge of physico-chemical properties and reactions is at hand.

The chemistry consists in giving the names of the compounds according to *Chemical Abstracts* nomenclature, portraying the structural formulas, which are given in great effusion and without arguments for or against, and for some compounds a few physical properties. Methods of isolation and preparation are not given. The volume would be more valuable to the chemist if the chemical data were more complete. The pharmacologic data are more complete than the chemical and are necessarily factual in nature. It must be pointed out that the size of the volume would soon get out of control if these subjects were treated more completely. From the pharmacologist's point of view the bibliography is excellent; from the chemist's it is incomplete. This volume and *Die Chemie des Pyrrols* by Dr. Hans Fischer and Dr. H. Orth would be complementary, as the one deals with pharmacology and the other with chemistry.

The format of the book will be welcomed. The printing process is photolithograph on a not too expensive paper. The binding appears to be well done but again with inexpensive materials. In this economical setup the printing is very legible, being clear, large and not crowded and, in addition, structural formulas and tables are not spared. Many scientifically valuable books may become financially possible if some such economical format becomes accepted.

**Pathology of the Nervous System: A Student's Introduction.** By J. Henry Biggart, M.D., Pathologist to the Scottish Asylums' Board. Foreword by Professor A. Murray Drennan, M.D., F.R.C.P. Cloth. Price, \$5.25. Pp. 335, with 204 illustrations. Baltimore: William Wood & Company, 1936.

This is written clearly and briefly and yet includes almost every entity one deals with in neuropathology. The author has succeeded in keeping together the relationship of the etiology to the pathology of each disease described. There is also a closer correlation between general pathology and the pathology of the nervous system than is found in most textbooks. The illustrations are excellent. The book is divided into fourteen chapters, on the nerve cells, the interstitial cells, the cerebrospinal fluid, vascular disease and the brain, acute bacterial infections, chronic infections, virus diseases, diseases of unknown etiology, intoxication and deficiency diseases, degenerative diseases, injuries to the nervous system, tumors of the glioma group, and errors in development. There is a small bibliography, but the works mentioned are in the

English language. This book is recommended to medical students as well as to those interested in the pathology of the central nervous system.

**Grundriss der Inneren Medizin.** Von A. von Demarus, a. o. Professor an der Universität Berlin. Tenth edition. Cloth. Price, 16.80 marks. Pp. 681, with 63 illustrations. Berlin: Julius Springer, 1936.

The first edition of this textbook of internal medicine appeared in 1923. The author is a pupil of the clinician and teacher Friedrich Müller. He has written this book on internal medicine as a guide to the young physician and medical student. He devotes 130 pages to the infectious diseases. Then follow circulatory diseases (seventy-three pages), respiratory diseases (sixty pages), blood diseases (twenty-five pages), diseases of the digestive tract (112 pages), of the urinary tract (fifty-two pages) and of the ductless glands (twenty pages), metabolic diseases (forty-eight pages) and diseases of the locomotor apparatus (twelve pages) and the nervous system (124 pages). The book has more information than most textbooks of its size, as a considerable portion is printed in small type. Some of the illustrations are in colors. The textbook is an excellent and concise outline of our present knowledge of internal diseases.

**Ballley's Text-Book of Histology** (Elwyn and Strong). Revised and rewritten by Philip E. Smith, Ph.D., Editor, Professor of Anatomy, College of Physicians and Surgeons, Columbia University, and others. Ninth edition. Cloth. Price, \$6. Pp. 773, with 506 illustrations. Baltimore: William Wood & Company, 1936.

The present revision is a cooperative undertaking of five members of the Anatomy Department of Columbia University College of Physicians and Surgeons. They have kept before them the fundamental idea that this was to be a textbook for students rather than a source book for teachers and research workers. They have endeavored to discuss the physiologic significance of the numerous structures described. The various revisers were assigned to those chapters in which they are most interested. The chapter on the central nervous system, written by Dr. Oliver Strong, which was revised in the last edition, remains unchanged. Some chapters have been entirely rewritten and many others have been brought down to date. This edition is well illustrated and a few of the illustrations are in colors.

**Experimental Enzyme Chemistry.** By Henry Tauber, Ph.D., New York Homeopathic Medical College and Flower Hospital, New York, N. Y. Fabrikoid. Price, \$3.50. Pp. 118. Minneapolis: Burgess Publishing Company, 1936.

This volume includes a number of highly technical essays on the chemistry of the enzymes under the following chapter headings: Physical Chemistry of the Enzymes; Esterases; Proteolytic Enzymes and Peptidases, Mammalian Gastric Proteases, Trypsins, Peptidases; Amidases; Carbohydrases, Sucrase (Saccharase, Invertase), Glucosidases, Maltases, Galactosidases, Lactase, Melibiase, "Emulsion," Polyases, Lichenase, Cellulase, Inulase; Catalase; Oxidizing Enzymes, Dehydrogenases or Anaerobic Oxidases, Oxidases or Aerobic Oxidases; The Flavine Oxidation System of Warburg and Christian and Its Relation to Other Dyes; Carbonic Anhydrase; The Zymase Complex and Alcoholic Fermentation; Luciferase. For all those interested in research in this field, it may be of special value; for the general reader, it is, of course, a book of reference.

**Über die Ursache und Entstehung des Krebses: Zugleich eine Anleitung zur Erschliessung des Zellbildes bösartiger Geschwülste.** Von Prof. Dr. med. Jos. Koch. Paper. Price, 32 marks. Pp. 302, with 32 illustrations. Jena: Gustav Fischer, 1936.

This monograph summarizes the results of Koch and his pupils on the protozoic etiology of cancer. Based on the examination of 260 human cancers and on transplantable animal cancers, he concludes that cancer is due to a protozoic organism, "cellula cancerosa specifica s. parasitoia," which enters through the intestinal and female genital tracts. "All phenomena in carcinoma, as manifold as they may be, can be related easily to one cause: the presence of the parasitic cell, and they can be satisfactorily explained by this." He discusses extensively the objections which have already been made in the literature and which, in most instances, are based on the conception of the wrong interpretation of degenerated products in cancer material, as parasitic specific cells. "To the chaos of

indecisive opinions and uncertain imaginations, I oppose my interpretation, which is able to relate the cytologic pictures to a uniform cause, namely, the existence of an exogenic protozoic cell parasite, and to interpret the pictures completely." In spite of the great amount of work and the excellent microscopic pictures (mostly colored), this book, written perhaps with honest enthusiasm but certainly without scientific criticism, will not solve the problem of the etiology of cancer. It particularly does not add any new information to further the still unsettled question of a relationship of living organisms to carcinogenesis.

**Exercises After Delivery or Operation.** By Walter B. Mount, M.D., Obstetrical Department, Mountinside Hospital, Montclair, N. J. Paper. Pp. 6, with illustrations. Privately printed, 1935.

In this booklet the author describes and illustrates a few conventional exercises for patients to take shortly after a delivery or operation. He promises his patients who carry out these exercises faithfully that they will the sooner regain their girlish figure.

## Bureau of Legal Medicine and Legislation

### MEDICOLEGAL ABSTRACTS

**Hospital Records as Privileged Communications.**—The defendant insurance company issued in April 1932 a policy on Vermillion's life, which was not to take effect if on the date of its delivery the insured was not in sound health. Vermillion died Nov. 14, 1932. When his beneficiary brought suit on the policy the company denied liability, claiming that at the time of the delivery of the policy the insured was "suffering from latent syphilis, chronic heart disease, swelling ankles, lues, nephritis, shortness of breath, cough frequency, and nocturia, and had been suffering from said ailments and was under the care of physicians for a long time prior" thereto and that as a result thereof the insured died of "heart disease and syphilis." To prove this it sought to introduce into evidence a case history made when the insured was admitted to a hospital about seven weeks after the delivery of the policy. The trial court excluded the hospital records proffered. Judgment was subsequently rendered in favor of the beneficiary and the insurance company appealed to the St. Louis (Missouri) court of appeals.

The defendant contended that the hospital records sought to be admitted in the trial court were admissible in evidence because they were kept in compliance with a Missouri statute (sec. 9056, R. S. Mo. 1929), requiring persons in charge of hospitals, public or private, to make a record of all the personal and statistical particulars relative to the inmates in their institutions. There is no doubt, answered the court of appeals, that hospital records, properly identified and shown to be kept pursuant to this statute, are admissible in evidence. However, the admissibility of such records may be affected by another statute (sec. 1731, R. S. Mo. 1929), which provides that a physician or surgeon shall be incompetent to testify "concerning any information which he may have acquired from any patient while attending him in a professional character, and which information was necessary to enable him to prescribe for such patient as a physician, or do any act for him as a surgeon." The defendant argued, however, that the trial court was not justified in assuming that the records were privileged merely on the assertion of counsel for the plaintiff that the information contained in those records was privileged and without proof of any kind being offered in support of that assertion.

It is true, said the court, that the mere assertion of the privilege, without any showing of facts or circumstances from which the court can determine the necessity for the application of the statute under which the privilege is claimed, is not sufficient to warrant a court in rejecting the proffered evidence or testimony. Nor is the mere relationship of physician and patient alone sufficient to warrant a court in rejecting, on the ground of privilege, evidence which would otherwise be competent. In the present case, however, the relationship of physician and patient and the fact that the information contained

in the case history was obtained by virtue of that relationship were sufficiently shown on the face of the case history itself to warrant the court in excluding it as a privileged communication. While it is true that the first page of the case history is not signed by any physician, such a signature was not necessary as a basis for the claim of privilege. The entries constituted a prima facie showing that the information was of a confidential and privileged character. If, as claimed by the insurance company, such information was not given by the patient to the hospital physicians for the purpose of enabling them to prescribe for the patient, then the burden was on the insurance company to produce evidence to satisfy the court to that effect and to overcome the prima facie showing of the confidential character of the information appearing therein.

In Missouri, continued the court of appeals, hospital records containing information obtained by a physician from a patient for the purpose of enabling him to treat or prescribe for the patient are as fully privileged as would be the testimony of the physician himself concerning such information, provided the privilege has not been waived by the party asserting it. The court was of opinion that the evidence contained in the case history was of a confidential nature acquired from the patient by the physician in charge of the hospital, or by physicians acting for him, for the purpose of enabling such physicians to treat the patient in the hospital, and that the trial court was warranted in rejecting such evidence. The judgment in favor of the beneficiary was accordingly affirmed.—*Vermillion v. Prudential Ins. Co. of America (Mo.)*, 93 S. W. (2d) 45.

**Workmen's Compensation Acts: Pneumonia Not an "Injury by Accident."**—Slade, after working indoors in an exceedingly hot environment, made several trips outdoors. That evening he became ill and on the following day his attending physician made a diagnosis of "consolidated pneumonia," which the physician testified was "due to sudden change of temperature, going from the hot room out into the open air. It produced a congestive chill." Slade died six days later and his widow instituted proceedings under the North Carolina workmen's compensation act. An award of compensation made by the industrial commission in her favor was reversed by the superior court, Cabarrus county, and the widow appealed to the Supreme Court of North Carolina.

The North Carolina workmen's compensation act, said the Supreme Court, provides compensation for death only where death results from an injury by accident arising out of and in the course of the employment. Death from injury by accident implies a result produced by a fortuitous cause. In the present case, said the court, there was no evidence of any accidental injury arising out of and in the course of employment which resulted in the death of the employee. Compensation was therefore properly denied the widow.—*Slade v. Willis Hosiery Mills (N. C.)*, 184 S. E. 844.

### COMING MEETINGS

- American Academy of Orthopedic Surgeons, Cleveland, Jan. 11-13. Dr. Philip Lewin, 55 East Washington St., Chicago, Secretary.
- American Orthopsychiatric Association, New York, Feb. 18-20. Dr. George S. Stevenson, 50 West 50th St., New York, Secretary.
- Annual Congress on Medical Education, Medical Licensure and Hospitals, Chicago, Feb. 15-16. Dr. William D. Cutter, 335 North Dearborn St., Chicago, Secretary.
- Eastern Section, American Laryngological, Rhinological and Otolological Society, Boston, Jan. 7. Dr. D. C. Jarvis, Quarry Bank Bldg., Barre, Vt., Chairman.
- Middle Section, American Laryngological, Rhinological and Otolological Society, Chicago, Jan. 11. Dr. Alfred Lewy, 25 East Washington St., Chicago, Chairman.
- Mid-Western Section, American Laryngological, Rhinological and Otolological Society, Chicago, Jan. 11. Dr. Frederick A. Figi, 436 Tenth Ave. S.W., Rochester, Minn., Chairman.
- Society of American Laryngologists, Rhinologists and Otolologists, Baldwin, College of Physicians, University of Wisconsin, Madison, Wis., Dec. 28-30. Dr. I. L. Baldwin, College of Physicians, University of Wisconsin, Madison, Wis., Secretary.
- Society of Surgeons of New Jersey, Newark, Jan. 6. Dr. Walter B. Mount, 21 Plymouth St., Montclair, Secretary.
- Southern Section, American Laryngological, Rhinological and Otolological Society, Memphis, Tenn., Jan. 13. Dr. Charles D. Blassingame, Physicians and Surgeons Bldg., Memphis, Tenn., Chairman.
- Western Section, American Laryngological, Rhinological and Otolological Society, San Diego, Calif., Jan. 30-31. Dr. David R. Higbee, 3245 Fourth Ave., San Diego, Calif., Chairman.

## Current Medical Literature

### AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers in continental United States and Canada for a period of three days. Periodicals are available from 1926 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them. Titles marked with an asterisk (\*) are abstracted below.

The Management of Alcoholism. H. H. Wilson, Los Angeles.—p. 349.

**Portal Thrombosis.**—Pallette discusses thrombosis of the portal venous system from the standpoint of etiology, symptomatology, frequency, pathologic physiology and treatment. The condition is too infrequently recognized as a clinical entity. The acute condition may closely simulate an abdominal emergency, and in the chronic form the associated splenomegaly should not be regarded as successfully amenable to surgical treatment. Unfortunately there is no treatment of any essential value in this condition. In acute cases the usual procedures for the treatment of shock, ileus and the like are instituted. In his own case the author felt that perhaps the repeated injections of intraspinal procaine hydrochloride given in the hope of relieving the marked ileus present was of considerable value and perhaps definitely influenced the outcome toward recovery. The basis for this opinion is that, in relieving the critical distention of involved intestine, the already embarrassed circulation to that loop is relieved. The huge ascites can be controlled by paracentesis. In the chronic cases, instructions should be given as to the avoidance of all alcoholic beverages or of any drug toxic in any way to the liver.

**New Sign in Transverse Lesions of Spinal Cord.**—In 1930 Kerr first noticed in a patient with a somatic sensory level due to a probable cord tumor that there was a change of the skin that could be felt. The skin above this level, which may be designated as normal, felt smooth, soft, moist and pliable and could be readily lifted between the thumb and forefinger. On the other hand, the skin below the level seemed stiff, "hide bound," dry and adherent to the subcutaneous layers, so that only with difficulty could a layer of skin be pinched together. It was found that this change could be sensed also by gently trying, with the tips of the extended fingers, to displace a segment of skin on its underlying tissues. Sometimes in patients studied subsequently the transition from normal to altered skin was abrupt, sometimes more gradual over one or two segments. Since 1930 Kerr and Noble have examined about 100 patients in the University of California Hospital and the San Francisco Hospital. The patient was usually in ignorance of the presence of any such level. Sixty-four subjects were examined presumably as normal controls. There were twenty patients with a somatic sensory level and other convincing evidence of disease of the spinal cord. Their diagnoses included both intramedullary and extramedullary tumors, transverse myelitis of degenerative or inflammatory origin, diffuse arachnoiditis and fracture of the spine. In these patients a level of skin tension was found

which was in fairly close agreement, either with that somatic sensory level or, more often, with a level of change in sweating or pilomotor response. In ten of these twenty patients the level of the process in the cord was confirmed by operation or necropsy or, in the case of spinal fracture, by roentgen examination. In nine of these ten the level of skin tension corresponded exactly with the area of disease and in one case pointed to a tumor five segments higher in the cord than indicated by the somatic sensory level. In this patient, whose first laminectomy had ended in a fruitless search for the lesion, operation confirmed the suggestion of a higher level of skin tension. In ten patients with evidence of disease of the spinal cord with a somatic sensory level, no level of skin tension could be demonstrated. That this sign might affect the halves of the body differently is shown by two patients. In one of these patients there was a unilateral hypertonus of the skin associated with marked constriction of the peripheral vessels on the same side, secondary to a cerebral lesion in the opposite hemisphere. A similar observation was made in a patient with a nearly complete Brown-Séquard syndrome due to a fracture of the cervical spine.

**Mandelic Acid in Treatment of Bacilluria.**—From July 1935 to September 1936 Budge has treated forty-six cases of bacilluria with mandelic acid and ammonium chloride with such satisfactory results that the ketogenic diet has been discontinued. There has been one known recurrence in a young woman who discontinued treatment against instructions. In a man, aged 43, there was the severe complication of hemorrhage with acute retention, probably from the false passage of a sound in an attempt to dilate a stricture; however, he was relieved of symptoms. With mandelic acid, as with the ketogenic diet, best results are obtained with a highly acid urine. Mandelic acid is readily taken and well tolerated by children. Success with the ketogenic diet in children can rarely be attained in the home. It is not necessary to hospitalize a child to administer mandelic acid. The standardized ketogenic diet can be readily prepared in any home; the patient when away must depend on eggs and 40 per cent cream, but mandelic acid can be carried in the grip. The patient who is placed on the ketogenic diet is told that he may expect to become sick on the second day and often it is necessary to stop the diet temporarily because of persistent nausea. The longer mandelic acid is taken, the better it is tolerated. The ketogenic diet is contraindicated in diabetes, angina, biliary tract disturbances and in elderly people with arteriosclerosis, but mandelic acid can be used in these conditions.

- \*Suggested Routine Technic for Emergency Tracheotomy. W. B. Chamberlin, Cleveland.—p. 800.

**Technic for Emergency Tracheotomy.**—Chamberlin declares that the Mosher tube answers the problem of relief of sudden and acute laryngeal obstruction. Its ease of introduction in either the erect or the reclining posture leaves nothing to be desired, while its lumen gives ample space for free respiration while the tracheotomy is being performed. The technic in the main is the same as that used in the introduction of an intubation tube, except that there is no introducer to be removed. The forefinger of the left hand is carried over the base of the tongue until the tip of the epiglottis is felt. In children it is much better to feel for the arytenoids, which are distinguished as two small lumps on the flexor surface of the index finger. This prevents the tube from slipping into the esophagus. The tube is carried along the flexor surface of the index finger until its point is directly above the opening of the larynx. The handle or proximal end is elevated and the tip, guided by the finger, is pushed gently through the larynx and into the trachea. After the tube has been introduced, it is held in position by a nurse or assistant to see that it is neither coughed out nor displaced. The patient is then placed in the usual position for the tracheotomy. Before the trachea is opened, all bleeding is carefully controlled and the field inspected to see that it is perfectly dry. The trachea is opened either between the rings or by cutting directly across one of them. In older patients in whom larger tubes are used it is generally advisable to resect a portion of the ring to prevent undue pressure from the tube. This piece should be firmly grasped with forceps or hemostat to prevent aspiration. A

blunt hook is then inserted through the opening and the trachea is drawn slightly upward. When the trachea is opened the convex surface of the Mosher tube, rather than the end, is usually brought into view. The tube is slightly withdrawn until the end appears above the first hook. Two other hooks are inserted, one on each side, and the tracheotomy tube is placed in position and firmly tied behind the neck. Two or more skin sutures may be necessary; also a small drain immediately above and below the tube to take care of superficial and late bleeding. The Mosher tube is then withdrawn.

- William Cline Borden (1858-1934). D. L. Borden, Washington.—p. 310.

**Traumatic Epilepsy with Cortical Scar.**—Rowe and Watts relate the diagnostic features of their twenty cases of traumatic epilepsy with a cortical scar. All the patients had received severe head injuries prior to the onset of epilepsy. There was loss of consciousness for many hours and often for many days. Emergency operations for elevation of depressed fractures and débridement had been performed in several instances. Bone defects, obvious both from clinical and from roentgen examination, were present in 65 per cent of the patients. Laceration of the dura was found at operation in 35 per cent. Focal features of the convulsive seizures were observed in 60 per cent of the patients. Neurologic signs indicative of focal cerebral damage were present in 85 per cent. These varied from slight defects in the visual fields to partial hemiparesis. Of the fifteen patients in whom encephalograms were made, observations indicative of cerebral cicatrix were present in thirteen. There was an interval of fourteen years in two of the patients between the injury and the first convulsion, of thirteen years in one patient and of twelve years in another. The shortest period between injury and the first attack was three months and the next shortest was seven months. Excision of the cortical scar resulted in only slight, temporary or no improvement in 35 per cent of the patients, whereas 15 per cent were entirely relieved of attacks, and an additional 50 per cent showed marked improvement. The fact that 65 per cent of the patients were definitely benefited seems to justify removal of the cortical scar in attacking what is otherwise a hopeless condition.

Medical Aspects of Social Hygiene in Montgomery County, Pa. R. A. Vonderlehr, Lida J. Usilton, Washington, D. C., and Helen Cole Carter, Norristown.—p. 21.

**Clinical Significance of Hoarseness.**—Wagers admonishes that hoarseness, particularly if unaccompanied by pain or a cough, is too often ignored by the patient and sometimes by the physician as well until such time as other and more alarming symptoms appear. Every case of hoarseness does not indicate a grave constitutional disease. But no matter how trivial the appearance of hoarseness may seem, it should always be regarded seriously. The immediate cause of hoarseness is found in various conditions affecting the proper functioning of the vocal cords. It becomes then the problem of the laryngologist to discover the immediate and if possible the remote or constitutional cause underlying and responsible for the local laryngeal manifestation. In all cases a careful and complete history should be the basis of the investigation, followed by inspection of the larynx, physical examination of the chest, roentgen study of the chest and the larynx, Wassermann test, and in certain instances microscopic study of removed laryngeal tissue. Frequently hoarseness or some other voice change is one of the first signs of pulmonary tuberculosis. Hoarseness may be and often is the first symptom indicating malignant invasion of the larynx. Nonmalignant neoplasms are frequently seen within the larynx. Most of those causing hoarseness are in close relation to the vocal cords themselves—either within the cord, projecting from its free margin, or located at the anterior commissure. Although many cases of hoarseness may be due to the presence of laryngeal tumors, malignant or benign, or to syphilis, tuberculosis and paralysis of different laryngeal muscles, it is not to be assumed that there is no such thing as simple acute or chronic catarrhal laryngitis. Cases of the former are often seen. They are usually of short duration and the result of various exciting causes. With the removal of the cause and rest of the voice, hoarseness quickly disappears in most instances. The simple chronic form of laryngitis is usually produced by long continued vocal abuse.

**Cerebral Toxic Pericapillary Hemorrhage.**—Helfand and Wolfson report a case of purpura of the brain that developed in the course of arsenamine treatment. Statistical studies reveal its presence once in every 1,500 treated cases and its

expectancy is one out of every 36,000 injections. The microscopic observations indicate that purpura of the brain may represent the end result of a series of causes entering more or less simultaneously into action. Some of the causes may be of a predisposing nature and others of a precipitating nature. In the authors' case the presence of chronic encephalitis and chronic alcoholism probably played the part of predisposing factors, which fact upholds Jakob's contention that in many cases of pericapillary hemorrhage one finds chronic syphilitic vascular changes or other preexisting vascular inadequacies. Alcohol and encephalitis may have determined the area of minor resistance. Arsenic must have played the part of a precipitating agent and may have acted both by damaging the endothelial lining elements of the small blood vessels and by producing through toxic mechanisms a damage of the perivascular tissue, thus creating one of the most essential factors in determining a hemorrhage of the brain; i. e., the presence of angiovascular and perivascular necrosis. To what extent chronic alcoholism is responsible for areas of demyelination is difficult to answer owing to the fact that both alcoholism and arsenical intoxication may result in the production of similar areas of demyelination. The term cerebral toxic pericapillary hemorrhage is preferred to encephalorrhagia, as it implies the suspected pathogenic mechanism of a toxic action in contrast to other forms of pericapillary hemorrhages in which hypertension and other factors may play an important part.

- \*Selenium Problem in Relation to Public Health: Preliminary Survey to Determine Possibility of Selenium Intoxication in Rural Population Living on Seleniferous Soil. M. I. Smith, K. W. Franke and B. B. Westfall.—p. 1496.

**Selenium Problem in Relation to Public Health.**—Smith and his co-workers made a survey of the rural population of parts of Wyoming, South Dakota and Nebraska to determine the possibility of selenium intoxication through the ingestion of locally produced selenium-bearing foodstuffs. A series of 111 families was studied for clinical evidence of selenium intoxication, and a series of 127 specimens of urine of as many subjects, representing ninety families, was analyzed for this element. The results of the urinary analysis showed that only 8 per cent of the cases were free or nearly free of selenium, while 92 per cent contained amounts varying from 2 to 133 micrograms of selenium per hundred cubic centimeters. This affords definite proof of the absorption of selenium by some of the rural population in the foregoing states. In the 111 families visited, the following disorders, exclusive of the more vague symptoms of anorexia, indigestion, general pallor and malnutrition, were observed: 1. Bad teeth, varying from marked discoloration through all stages of decay, were seen in one or more members of forty-eight families. 2. Yellowish discoloration of the skin, in many cases a very definite icterus, and in some cases seemingly associated with more or less definite liver disease, was seen in about forty-six subjects. 3. Skin eruptions of varying degrees of severity, but not conforming to any one particular type, were seen in twenty subjects. 4. Chronic arthritis with more or less permanent changes in the joints was present in fifteen subjects, varying from the milder types of rheumatoid arthritis to the more severely deforming type of arthritis deformans. 5. Diseased nails of the fingers, and in some cases also of the toes, were observed in eight subjects. They were usually symmetrical, atrophic, brittle and irregular and often presented transverse and at times longitudinal ridging. 6. Subcutaneous edema of probably cardiorenal origin was diagnosed in five cases, and peripheral neuritis of doubtful etiology in two subjects. Fifteen subjects gave a history of more or less protracted gastro-intestinal disturbances.

**Diphtheria Toxin Production.**—Pappenheimer and Johnson were led to reinvestigate the effect of inorganic salts on toxin production by the accidental observation that the yield of diphtheria toxin produced on infusion-free peptone medium increased by more than 100 per cent when Fernbach flasks made of soft glass were used instead of the usual pyrex glass. It was thought that this stimulation of toxin formation might be due to the copper or iron content of the soft glass, and these metals were accordingly studied in detail. The variation in toxin production from flask to flask, from one batch of medium to another, and the frequent inability of one laboratory to produce toxin on mediums recommended by others, may often be attributed to the variation in the concentration of iron salts in mediums and flasks. The amount of iron necessary to prevent diphtheria toxin formation is considerably less than the amount found in normal tissues. It is therefore significant that all methods for preparing toxin mediums involve the removal of a flocculent precipitate formed in alkaline solution. Excess iron is presumably removed at this point. All mediums giving a visible color test for iron with dipyrindine have failed to produce any diphtheria toxin. It has often been claimed that no relationship exists between growth and toxin production; however, if the inorganic salt concentration is suitably controlled, a relationship may be found.

**Bactericidal Power of Blood in Presence of Inflammation.**—Hughes observed that the bactericidal power of normal blood does not fall in vitro within six hours. The blood of patients with active bacterial disease shows a steady loss of bactericidal power. Normal persons, when given vaccine, show a similar change during the stage of reaction. Blood drawn during a rigor shows one of two changes: if it is drawn at the beginning of the rigor, there is a constant low level of bactericidal power without further loss on standing; if it is drawn later, it shows a bactericidal power below normal and a progressive loss in vitro. Blood drawn after the rigor is normal. A mixture of serum taken from a patient with active bacterial disease or with an artificially produced reaction and normal blood cells shows a constant low bactericidal power with no further deterioration. The hypothesis that a toxic substance is present in the blood of patients having certain diseases, which, when it is first liberated, exerts an inhibitory effect on the bactericidal power both of normal corpuscles and of the patient's own corpuscles would appear to account for these results. The nature of the substance is at present unknown; it has been impossible to initiate the gradual loss of power by adding known substances to the drawn blood; e. g., bacterial toxin, autolyzed bacteria, filtrate of pus, or histamine. When a change followed the addition of any of

these substances, it was a reduction once for all of the bactericidal power, similar to the effect of the patient's serum on normal corpuscles or of the onset of rigor. This suggests that two factors may be responsible for the gradual deterioration of certain bloods, one the toxic action of a substance liberated during the inflammatory reaction, the other an adjustment of the body to that substance. The best indication of the presence of the substance in the patient's blood was his general condition; some indication is given by the temperature, the deterioration usually being shown if this is raised.

**Hodgkin's Disease and High Voltage Roentgen Therapy.**—Watt reviews 201 cases of Hodgkin's disease treated from 1923 to 1934. General medical treatment is extremely important throughout the whole course of the disease. Arsenic should not be given during or until six weeks after a course of irradiation. Surgical removal of glands except for emergencies appears to be of no permanent value. Ordinary x-rays act well as long as the glands are localized and superficial. Cases so treated respond afterward to high voltage irradiations just as well as untreated cases. High voltage roentgen therapy is recommended because the response to treatment is much quicker, and by varying the voltage and filtrage to suit the glands to be treated one can in a short time treat masses of glands no matter where they are situated. For superficial glands a voltage of from 160 to 170 kilovolts is sufficient, combined with aluminum filters or the equivalent of from 5 to 6 mm. thickness. A depth dose of 60 per cent of the skin erythema dose is usually enough. The spleen if palpable should receive a similar amount of radiation. The first irradiation should usually cover all the affected areas and may be spread over a period of from a week to a month if necessary. Any recrudescence should be treated at the earliest possible moment. The active focus can usually be found in persistent pyrexia. In this way, after the initial long treatment, patients are as a rule able to carry on their ordinary activities and duties with nothing but an occasional single irradiation to interfere. Periodic inspection of patients cannot be too strongly emphasized.

Mucous Colitis. J. R. Goodall.—p. 925.  
Some Unusual Cases of Twin Pregnancy. Elizabeth M. Moore.—p. 936.

**Mesodermal Mixed Tumors of Uterus.**—Meikle reviews the literature on mixed tumors of the uterus, which are rare, and reports a new case. These tumors are composed of mixed tissues of mesodermal origin, being analogous to similar tumors found in other situations, for example the kidney and parotid gland, and only tumors including mixed tissues, as opposed to those containing mixed cells, are discussed. The mixed tissues found in these tumors are essentially heterotopic to the uterus and the tumors are highly malignant. They should not be confused with other tumors containing mixed tissues derived from a degenerative process, such as fibromyomas exhibiting fatty degeneration or calcification. Corporeal tumors are more common than those of the cervix, in contrast to the statements of other writers. There is a similarity of the age incidences in carcinoma and mixed tumor occurring in the body and in the cervix of the uterus. It is hypothesized that these tumors arise from cell rests probably activated by hormone disturbances. Of the various forms of treatment discussed, preference is given to radical surgery with postoperative roentgen therapy. The mortality is more than 90 per cent and death occurs in most cases within two years.

Premenstrual Temperature Rise in Pulmonary Tuberculosis. R. Weiller.—p. 309.

**Premenstrual Elevation of Temperature in Pulmonary Tuberculosis.**—Weiller states that in a large number of perfectly healthy women the menstrual periods are preceded by a slight elevation of body temperature. In patients with pulmonary tuberculosis this premenstrual rise in temperature is almost constant, and the degree to which it rises varies, depending on the individual case. In patients having healed lesions the temperature reaction is slight and analogous to that observed in healthy women. In patients with active lesions the temperature reaction is more marked, sometimes approaching a true fever. Since the degree of temperature rise is roughly parallel to the activity of the tuberculous process, the author believes that it has some prognostic significance. The explanation for this phenomenon is somewhat obscure, but several pathogenic factors enter into its causation. Menstrual detoxification, discharges of hormone and bacillemia all play an important part in the thermal instability so characteristic of pulmonary tuberculosis.

**Treatment of Articular Fractures by Procaine Hydrochloride.**—Leriche and Froehlich describe their method of treatment of articular fractures without displacement or not requiring exact reduction, by means of infiltration of the neighboring ligaments with procaine hydrochloride. By this means they hoped to block the vasomotor phenomena which tend to create a secondary arthritis and to allow active immediate motion because of the absence of pain. They obtained results which passed even their expectations. Their patients recovered with great ease in a short time and with maximal functional results. The effect of each infiltration lasts from twelve to twenty-four hours, and they repeated their injections as often as necessary. Three examples of this procedure are reported in detail. In each the results were exceptionally good. The authors believe that this method has a wide margin of application in all cases in which it is not necessary to reduce the fracture and maintain the reduction by appliances. It is curious to see how much the immediate return to function and the suppression of pain improve the quality of the results. Simple surgical common sense suffices to mark the limits of immediate mobilization after such fractures.

Weil's Disease in Switzerland. O. Gsell.—p. 702.

Significance of Determination of Diameter of Erythrocytes with Especial Consideration of Carcinoma and Ulcer of Digestive Tract. A. Alder and N. Markoff.—p. 709.

**Electrocardiographic Changes After Work Test in Disturbances of Coronary Circulation.**—Duchosal and Henny cite authors who made electrocardiographic studies in connection with the so-called work test in the diagnosis of disorders in the coronary circulation. To estimate the reliability of this test, they made it on ninety subjects: thirty-seven normal persons, ten patients with cardiac defects but without

coronary disorders, nineteen patients with proved angina pectoris and twenty-four doubtful cases of angina pectoris. A tabular report indicates that in each of the first two groups there was one positive case. Of the nineteen patients with proved angina pectoris, eleven gave positive tests, one a doubtful one and in the remaining seven the outcome was negative. Of the twenty-four doubtful cases of angina pectoris, seven gave positive and four doubtful tests, while in the other thirteen the outcome was negative. The authors analyze these results and conclude that the work test in connection with electrocardiography has diagnostic value in the doubtful cases of angina pectoris. They think that the positive work test indicates disturbances in the blood perfusion of the myocardium but does not necessarily imply the existence of anatomic lesions in the coronary vessels.

**Weil's Disease in Switzerland.**—Gsell directs attention to an increase in cases of Weil's disease. Investigations in four proved and one suspected case during the summer of 1935 indicated that infestation of rivers with rats might be responsible for these cases. Some of the patients had bathed in rat-infested waters, but the author points out that working on canals or the intake of contaminated drinking water or food may likewise be a factor. He further directs attention to the fact that an increased incidence of Weil's disease has been reported also from other countries. In the completely developed cases the diagnosis is not difficult, but the abortive forms are harder to recognize. He thinks that in cases in which there are high fever, hepatorenal impairment, leukocytosis, early and great acceleration of the sedimentation speed of the erythrocytes, irritation of the bone marrow and a tendency to hemorrhagic diathesis, Weil's disease should be thought of and serologic tests should be made. The condition should be differentiated from catarrhal icterus, which usually takes its course without fever, renal involvement, increased sedimentation speed and leukocytosis. For the treatment of Weil's disease the author recommends convalescent serum, blood transfusion, infusion of fluids (to compensate for the loss of fluids), rabbit immune serum and bismuth-chiniofon.

**Diameter of Erythrocytes in Carcinoma and Gastric Ulcer.**—Alder and Markoff determined the mean size of the erythrocytes in 100 cases of carcinoma or ulcer of the digestive tract. In the majority of cases of gastric carcinoma they observed that a macrocytosis develops relatively early; that is, at a time when neither anemia nor anisocytosis is observable as yet. Location or duration of the carcinoma, age of the patient, existence of hepatic metastases or the state of the secretory action of the stomach has no influence on the macrocytosis. The authors think that a toxic influence on the blood formation is responsible for the development of the macrocytosis. They are convinced that a deficiency of the intrinsic factor of the antianemic principle cannot be the causal factor, because the macrocytosis is absent after gastric resection on account of ulcer but it is present in patients in whom resection has been done on account of carcinoma. They conclude that the determination of the mean diameter of the erythrocytes may in some cases be of value in the differential diagnosis of gastric carcinoma.

## Giornale Veneto di Scienze Mediche, Venice

10: 645-712 (Oct.) 1936

**Injection of Irradiated Blood.**—Boggian reports satisfactory results from the administration of intramuscular injections of citrated blood subjected to ultraviolet irradiation in more than 216 patients suffering from skin diseases, acute or chronic anemia and various forms of rheumatism. The author says that the material used in the procedure should be sterilized. The layer of blood in the petri dish to be irradiated should be thin. The blood is frequently mixed by tipping the dish in the horizontal and oblique positions. For the irradiation (from

half a minute to two minutes) a modified Hanan's lamp (Bactophos) is employed. The blood is then injected in increasing doses of from 2.5 to 15 or 30 cc. for each injection. The injections are administered slowly three times a week until fifteen injections have been given. A solution of citrate can be added to the blood for maintaining its fluidity. Adding anesthetic solutions to the blood frequently results in the formation of local abscesses and diminishes the stimulating properties of the blood. The author used heterotherapy. He concludes that on ultraviolet irradiation a substance appears in the blood which stimulates the formation of erythrocytes and hemoglobin, except after splenectomy. The substance is a hormone not yet identified which exists in the blood plasma but not in blood serum. It originates in the erythrocytes, is labile to ultraviolet irradiations and paraformaldehyde and favorably modifies the consistency of the bone marrow. The failure of irradiated blood to stimulate erythropoiesis in splenectomized animals shows that the substance does not exist in the blood after splenectomy and confirms the fact that there is a relation of interdependence between the spleen and the bone marrow in the processes of erythropoiesis. The rapidity and intensity of the erythropoietic reaction of the patient to the injection depends on the amount of stimulating substance contained in the injected blood, which in turn depends on the number of erythrocytes in the donor's blood.

Gastroduodenal Ulcer. L. Zoja.—p. 401.

Anatomic and Clinical Study of Extrapleural Pneumothorax. C. Rotta.—p. 404.

\*Favism: Skin Reaction in Forty-Four Cases. M. Pazzi Demurtas.—p. 411.

**Skin Reaction from Bean Extracts in Favism.**—Pazzi Demurtas made skin reactions with extracts of beans on forty-four persons of various ages who were suffering from favism. The author states that there are three different allergens in the beans; the first is found in the flowers, the second in the seed, the coat and the shell of the beans and the third in the parasites of dry beans or in the remaining fractions of parasites in the beans. The seed allergen is the same as that of the flowers but is modified during the process of maturation of the plant, and through the modifications its biologic properties are changed. The flower allergen is more volatile than that of the seed, but the seed allergen is more concentrated. Bean allergens lose their biologic action as the beans dry up. But, as beans dry up, parasites appear within them which contain allergens with the same hypersensitizing properties as the allergens of the plant and of fresh beans. The hypersensitivity produced by the parasite does not show itself with the grave symptoms of jaundice and hemoglobinuria that are characteristic of typical favism. The symptoms are benign and sometimes there are no symptoms at all caused by parasitic hypersensitization. This is due to the biologic characteristics of the parasite. Patients who suffer a serious attack of favism are temporarily desensitized. During the period of desensitization they give negative skin reactions to the allergen that caused the attack. Desensitization in these cases is not caused by general anergy. When the patient is sensitive to various allergens the skin reaction is negative only to the allergen that caused the attack and positive to all other allergen extracts. When the patient again becomes sensitive to the allergen that caused the attack, the skin reaction becomes positive again. Some hypersensitive persons lose their hypersensitiveness after a given lapse of time. The skin reaction in these persons is never negative.

### Policlinico, Rome

Cholesterinic Lipoidosis: Case. E. Tarantelli.—p. 556.

Pathogenesis of Favism. A. Luisada.—p. 579.

**Cerebrospinal Fluid in Tetanus.**—Liberti states that the inoculation of large doses of cerebrospinal fluid (17 cc.) from patients suffering from tetanus failed to give tetanus to the

inoculated guinea-pigs. The same negative results were obtained when the cerebrospinal fluid used in the experiment was taken after prolonged anesthesia of the patient in aseptic meningitis. The presence of antitoxin in the cerebrospinal fluid of patients suffering from tetanus who were treated by intramuscular administration of antiserum was verified. The amount of antitoxin in the cerebrospinal fluid was small compared to that in the blood, as was manifested by the antitoxic power of the blood on the one hand and of the cerebrospinal fluid on the other. The antitoxic power of cerebrospinal fluid is proportional to the intensity of meningeal irritation. It can be greatly increased by inducing meningeal irritation in the patient. According to the author, the results of the experiments prove that the toxins do not pass into the cerebrospinal fluid in tetanus and that the antitoxins pass into the fluid during antiserum treatment.

### Brasil-Medico, Rio de Janeiro

50: 969-990 (Nov. 7) 1936

\*Modified Staining Technic for *Spirochaeta Pallida* in Smears. A. G. de Castro Cerqueira.—p. 969.

Suggestion and Hypnotism. A. M. Langsner.—p. 976.

Foreign body in Respiratory Tract: Case. T. Falcão.—p. 981.

**Staining Technic for *Spirochaeta Pallida*.**—De Castro Cerqueira describes a modification of Hollande's technic for identification of *Spirochaeta pallida* in smears prepared from the exudates of suspected lesions. The modification consists in staining the smears with Ziehl's carbolfuchsin (instead of impregnating them by a solution of silver nitrate) and diminishing the concentration of glacial acetic acid of the original technic. *Spirochaeta pallida* stains smoothly and completely a clear violet pink, whereas the microscopic field stains a reddish violet. The author examined more than 2,796 smears from exudates. *Spirochaeta pallida* was identified in 14.51 per cent of the cases. The low percentage of positivity is due to the fact that smears were made systematically in all cases of ulcerations and excoriations of the skin and mucosa seen by the author, especially those on the genital organs, regardless of symptoms of syphilis. In several cases the positive results of the test preceded the appearance of characteristic clinical symptoms of syphilis and of chancre. The technic is simpler and more effective than other technics for identification of spirochetes, including Hollande's.

Operative Treatment of Simple Fractures. O. Kingreen.—p. 401.

**"Fish Vertebra" Disease.**—Brandt is inclined to consider a type of osteomalacia of the vertebral column, characterized by hour glass or "fish vertebra" deformity, an independent entity. The disease has an insidious onset with ill defined pains along the entire vertebral column, more pronounced over the lower thoracic and upper lumbar vertebrae. Examination reveals a mild kyphosis, which may be associated with a kyphotic projection of the spinous processes in the region of the tenth thoracic to the second lumbar vertebra. Blood calcium is normal or increased. Roentgenologic examination is of decisive value in the diagnosis. Stereoscopic plates taken in two planes, the anteroposterior and the lateral, reveal a lack of calcium in all the vertebrae, as well as in the bones of the pelvis and the lower extremities. The lateral view demonstrates the fish vertebra-like deformity. The pathogenesis is explained on the basis of softening of the substance of the body of the vertebra, the characteristic deformity resulting from the pressure of the intervertebral disks, which remain normal. The author proposes that this disease picture be considered an independent clinical entity to be differentiated from a purely symptomatic similar deformity caused by tumor metastases, multiple myeloma, infectious spondylitis or trauma.

## SECTION OFFICERS

**PRACTICE OF MEDICINE**—Chairman, John H. Musser, New Orleans; Vice Chairman, Ralph H. Major, Kansas City, Mo.; Secretary, Joseph T. Wearn, 2065 Adelbert Road, Cleveland.

**SURGERY, GENERAL AND ABDOMINAL**—Chairman, Robert S. Dinsmore, Cleveland; Vice Chairman, Alton Ochsner, New Orleans; Secretary, Henry W. Cave, 107 East 67th Street, New York.

**OBSTETRICS, GYNECOLOGY AND ABDOMINAL SURGERY**—Chairman, M. Pierce Rucker, Richmond, Va.; Vice Chairman, Buford G. Hamilton, Kansas City, Mo.; Secretary, Everett D. Plass, University Hospitals, Iowa City.

**OPHTHALMOLOGY**—Chairman, William L. Benedict, Rochester, Minn.; Vice Chairman, Emory Hill, Richmond, Va.; Secretary, Parker Heath, 1553 Woodward Avenue, Detroit.

**LARYNGOLOGY, OTOTOLOGY AND RHINOLOGY**—Chairman, Robert F. Ridpath, Philadelphia; Vice Chairman, LeRoy A. Schall, Boston; Secretary, Gordon B. New, 102 Second Avenue S.W., Rochester, Minn.

**PEDIATRICS**—Chairman, Ralph M. Tyson, Philadelphia; Vice Chairman, Aldrich C. Crowe, Ocean City, N. J.; Secretary, Albert D. Kaiser, 16 N. Goodman Street, Rochester, N. Y.

**PHARMACOLOGY AND THERAPEUTICS**—Chairman, N. C. Gilbert, Chicago; Vice Chairman, R. L. Haden, Cleveland; Secretary, Irving S. Wright, 115 E. 61st Street, New York.

**PATHOLOGY AND PHYSIOLOGY**—Chairman, W. E. Garrey, Nashville, Tenn.; Vice Chairman, R. R. Kracke, Atlanta, Ga.; Secretary, J. J. Moore, 55 E. Washington Street, Chicago.

**NERVOUS AND MENTAL DISEASES**—Chairman, Henry R. Viets, Boston; Vice Chairman, B. Landis Elliott, Kansas City, Mo.; Secretary, Paul C. Bucy, 950 E. 59th Street, Chicago.

**DERMATOLOGY AND SYPHILOLOGY**—Chairman, Paul A. O'Leary, Rochester, Minn.; Vice Chairman, Charles C. Dennie, Kansas City, Mo.; Secretary, Bedford Shelnire, 1719 Pacific Avenue, Dallas, Texas.

**PREVENTIVE AND INDUSTRIAL MEDICINE AND PUBLIC HEALTH**—Chairman, L. D. Bristol, New York; Vice Chairman, J. F. Bredeck, St. Louis; Secretary, I. C. Riggins, State Office Building, Richmond, Va.

**UROLOGY**—Chairman, Henry W. E. Walther, New Orleans; Vice Chairman, Nelse F. Ockerblad, Kansas City, Mo.; Secretary, William P. Herbst, 1726 I Street N.W., Washington, D. C.

**ORTHOPEDIC SURGERY**—Chairman, Fremont A. Chandler, Chicago; Vice Chairman, John Dunlop, Pasadena, Calif.; Secretary, Robert V. Funsten, University of Virginia Hospitals, Charlottesville, Va.

**GASTRO-ENTEROLOGY AND PROCTOLOGY**—Chairman, Louis A. Buie, Rochester, Minn.; Vice Chairman, Henry L. Bockus, Philadelphia; Secretary, A. H. Aaron, 40 North Street, Buffalo.

**RADIOLOGY**—Chairman, Ross Golden, New York; Vice Chairman, B. R. Kirklm, Rochester, Minn.; Secretary, John T. Murphy, 421 Michigan Street, Toledo, Ohio.

\* Deceased.

# JOURNALS ABSTRACTED IN THE CURRENT MEDICAL LITERATURE DEPARTMENT, JULY-DECEMBER, 1936

Abstracts of important articles in the following journals have been made in the Current Literature Department of THE JOURNAL during the past six months. Any of the journals, except those starred, will be lent by THE JOURNAL to subscribers in continental United States and Canada and to members of the American Medical Association for a period not exceeding three days. Two journals may be borrowed at a time. No journals are available prior to 1926. Requests for periodicals should be addressed to the Library of the American Medical Association and should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Thus most of these journals are accessible to the general practitioner.

## SUBJECT INDEX

This is an index to all the reading matter in THE JOURNAL. In the Current Medical Literature Department only the articles which have been abstracted are indexed.

The letters used to explain in which department the matter indexed appears are as follows: "BI," Bureau of Investigation; "E," Editorial; "C," Correspondence; "ME," Medical Economics; "ab," abstract; the star (\*) indicates an original article in THE JOURNAL.

This is a subject index and one should, therefore, look for the subject word, with the following exceptions: "Book Notices," "Deaths," "Medicolegal Abstracts" and "Societies" are indexed under these titles at the end of the letters "B," "D," "M," and "S." State board examinations are entered under the general heading State Board Reports, and not under the names of the individual states. Matter pertaining to the Association is indexed under "American Medical Association." The name of the author, in brackets, follows the subject entry.

For author index see page 2218.

- muscular (pseudohypertrophic), hereditary aspect, [Hough] 622—ab

## DEATHS

## A

Abernathy, Hayes, 1654  
Ackerman, James Franklin, 892  
Adams, Alpheus Eli, 1404  
Adams, Royal Stuart, 1906  
Aday, Admiral Dewey: See Aday, Dewey  
Aday, Dewey, 893  
Adlerman, Theodore Davis, 1404  
Adrian, Frank W., 1068  
Alieu, Albert Frank, 984  
Allen, Albert Mayfield, 1404  
Allen, Harold McClellan, 1826  
Allen, Howard, 1404  
Allen, J. Edwin, 55  
Allen, Nathaniel Norris, 1907  
Allen, Roy William, 146  
Allen, William Joseph, 1652  
Allison, John Isaac, 984  
Altman, Louis Gilbert, 808  
Ambrister, Joe C., 729  
Ames, Arthur Eugene, 1984  
Ames, Elwin Witt, 146  
Ammond, Henry M., 604  
Amster, Ludwig, 1068  
Amunson, Philip B., 2068  
Anders, James Meschter, 806  
Anderson, Carl Johann, 1068  
Anderson, Clyde Oscar, 228  
Anderson, Edwin Clinton, 1403  
Anderson, Finis Logan, 807  
Anderson, Guy Collins, 1404  
Anderson, Harry Edward, 146  
Anderson, John E., 1404  
Anderson, Meriwether Lewis, 1403  
Anderson, Thos. Eli, 445  
Anthony, George Chinery, 2066  
Argy, Nicolas, 2068  
Armstrong, Francis Kennedy, 2067  
Armstrong, William H., 146  
Arseneau, Joseph Camille Eugene, 146  
Artz, Jerome L., 893  
Ash, Elmer E., 1403  
Ashbrenner, James H., 1984  
Askenafi, Samuel Flisler, 1148  
Atkins, Lloyd R., 2067  
Atkinson, Robert E., 146  
Atkinson, Wilfred Lorne, 1654  
Aukes, Elmer E., 1068  
Auremma, Salvatore, 1404  
Averitt, Horace Osler, 730  
Axford, Walter James, 808  
Axtell, John L., 146  
Ayres, Samuel, 1403

## B

Bacon, Charles P., 893  
Bacon, Joseph Barnes, 1067  
Bahl, William Henry, 54  
Bailey, Curtis Albert, 1068  
Bailey, George Samuel, 228

Research, Inc., new corporation to finance health department research, 721  
resort (modern), possibilities, [Wallace] \*419  
resort, spa treatment of rheumatic diseases, [Buckley] 2092—ab  
rural contest, winners in, 46  
rural meetings, Iowa, 1642  
rural, service, in U. S., 799  
Service: See also Health, rural  
service in invalid insurance, Germany, 1733  
service, student, 795—ME  
Statistics: See Vital Statistics  
Student: See also Health service  
student, selecting healthy ones, Germany, 51  
student, studied by American Youth Commission, 1899  
U. S. Public Health Service (changes), 47, 291, 800, 1479; (Internships available), 47  
Unit: See also Health center  
unit (first county established, Wis.), 799; (new, R. I.), 799; (new, Tenn.), 799  
**HEARING:** See also Deafness  
aids, electrical, [Hartig] 538—ab  
aids, prescribing, 511  
defective, state care, Switzerland, 980  
Haid of Hearing: See Deaf  
test, electro-acoustic apparatus for, 2145  
test, whisper, 1741  
treatment, Otioflex (device for generating tones), 499  
**HEART:** See also Arteries, coronary; Cardiovascular System; Pericardium; etc.; Medicolegal Abstracts at end of letter M  
action, erythema in adolescents, 223  
Auricular Fibrillation: See Auricular Fibrillation  
auricular sounds in normal and pathologic conditions, [Bramm Menendez] 84—ab  
auriculoventricular dissociation (complete), 294  
block, Stokes-Adams syndrome after influenza, [Mares] 1000—ab  
blood supply to, established by operation, [Beck] 1392—ab  
changes in carbon monoxide poisoning, [Litzner] 320—ab  
chloral hydrate effect on, [Alstead] 243—ab  
complications, in hyperthyroidism, operative results, 1234  
Disease: See also Cardiovascular Disease; Endocarditis; Pericarditis  
disease, A. M. A. symposium on, Atlantic City Session, 1816

**HEART—Continued**  
disease, acute pulmonary edema of cardiac origin, 1743  
disease and pregnancy, [Jensen] \*329  
disease and tobacco, 521  
disease, annual symposium, California, 1475  
disease, auricular fibrillation in, [Luten & Jeffreys] \*2099  
disease (chronic), total thyroidectomy for, [Riseman] 1000—ab  
disease (congenital), recognition, 41—E  
disease, emboli, [Gettner] 1338—ab  
disease, errors in interpretation, [White] 744—ab  
disease (fatal), acetylsalicylic acid factor in increase, [Temple] 164—ab  
disease, hospitals approved for residences in cardiology, \*703  
Disease, Hypertensive: See Blood Pressure, high  
disease, oxygen and thyroid ablation in, [Barach] 461—ab  
disease, pregnancy in, 231  
disease (rheumatic), disappearance of physical signs, [Bland & others] \*569  
disease (rheumatic) in children, [Ruprecht] 541—ab  
disease (rheumatic), T wave in lead 4 in children with, [Robinson] 1161—ab  
disease, roentgen kymography, [Scott & Moore] \*1951  
disease, total creatinemia in, [Messina] 244—ab  
disease, van den Bergh reaction in, [Gloriano] 1175—ab  
disorders (circulatory) due to pneumonia, [Gartrell] 1420—ab  
disorders (orthostatic circulatory), electrocardiogram in, [Akesson] 90—ab  
dynamics in paroxysmal tachycardia, 523  
electrocardiogram in coronary thrombosis, [Feldman] 745—ab  
electrocardiogram, significance of waves in, [Knoll] 915—ab  
electrocardiographic, selection, 1408  
electrocardiographic aspects of so-called nervous heart, [Eckey] 916—ab  
electrocardiographic studies in eclampsia, [Eufinger] 88—ab  
Electrocardiography: See also Heart, disease; Heart muscle  
electrocardiography, leads from thoracic wall in, [Hecht] 752—ab  
enlargement, digitals to prevent, 524  
enlargement, murmurs, disappearance in rheumatic heart disease, [Bland & others] \*569  
factors in lung disorders, [Oppenheimer] 2081—ab  
Fetal: See Heart sounds  
fever therapy effect on, [Krusen] \*1219  
function during fever therapy, [Owens] \*1944  
function, quantitative evaluation, Viola's serial method, 1236  
Hypertrophy: See Heart enlargement  
inflammation (rheumatic carditis), [Efinger] 89—ab  
inflammation (rheumatic carditis), electro-pyrexia for, [Neymann & others] \*938  
injury, [Elkhi] \*182  
Insufficiency: See also Asthma, cardiac  
insufficiency, blood metabolism and urobilinuria in, [Ehrstrom] 246—ab  
insufficiency, blood viscosity in failure, 504—E  
insufficiency, clinical use of diuretics, [Haymau] \*1937; [Kelth] \*2047  
insufficiency, failure in acute infectious diseases, drug treatment, [Eggleston] \*1213  
insufficiency, relation to tachycardia, [Luten] 2081—ab  
insufficiency, treatment of failure, [Wunderly] 1173—ab  
insufficiency, treatment of weakness, 726  
insufficiency, use of digitals in failure with beat below 60 and moderate edema, 1584  
lesion, relation to tonsillectomy, 301  
load, measuring, 59  
Muscle: See also Myocarditis  
muscle, creatine in pregnancy and hyperthyroidism, [Bodansky] 1166—ab  
muscle disorders, electrocardiographic diagnoses, 727  
Neurosis: See Asthenia  
palpitation, etiology, 152  
precordial pain, syphilis and heart disease, 448  
revital (postmortem) by cannula perfusion of coronary vessels, [Kountz] 1669—ab  
roentgen kymography, [Scott & Moore] \*1951  
roentgen study, actinocardiogram in mitral defects, [Beckmann] 834—ab  
size, x-ray measurement, epicardial fat cause of error in, [McGinn & White] \*200  
sounds, fetal tones in abattoir placenta, [Richardson] 1668—ab  
specialists, conventions, Italy, 1236  
stimulants in infectious diseases, [Smith] 819—ab  
syncope, pathology, [Nathanson] 2001—ab  
Valve: See also Aortic Valve; Mitral Valve  
valve, defects and life expectancy, [Friedmann] 1177—ab

**HEART—Continued**  
valve, hemorrhage into leaflets of atrioventricular valves, [Clark] 2085—ab  
valve rings, lesions in rheumatic fever, [Gross] 1163—ab  
**HEART OF AMERICA Brand Tomato Juice**, 1811  
**HEAT:** See also Cold; Temperature  
applied to serum as practical birth control measure, 1493  
cold or heat for pain of appendicitis, 230  
decomposition of dyes, dermatitis in phone cable splicers due to, [Schwartz] .79—ab  
effects on the human body, 1892—E  
for pain of appendicitis, 230  
hot climate, leukocyte picture (normal) in, [Kennedy] 2092—ab  
hot weather, deaths from, 363; 884  
lamp (simple, inexpensive), [Krusen] \*780  
Prostration: See Medicolegal Abstracts at the end of letter M  
radiant, cabinets, etc., for inducing fever, [Krusen] \*1215  
regulation in anhidrosis, [Fog] \*2040  
Therapy: See Blood Vessels, diseases; Diathermy, short wave; Rhinitis, atrophic; Skin tuberculosis  
**HEATSTROKE:** See Medicolegal Abstracts at the end of letter M  
**HEBERDEN Nodes:** See Nodes  
**HEGEL, GEORGE W. F., Mrs. Eddy purloins** from, 1620—ab  
**HEIDELBERG:** See University  
**HEIGHT:** See under Body  
**HELIOGRAVURE**, injurious effects of, 889  
**HELIOTHERAPY** and alkali reserve, [Morgan] 392—ab  
**HELIUM**, therapeutic use, [Barach] \*1273  
**HEMANGIO-ENDOTHELIOMA**, intravascular, of ovary, [Fujii] 2006—ab  
**HEMANGIOMA**, benign metastasizing, [Robinson] 1921—ab  
of eyelid, [O'Brien & Braley] \*935  
**HEMATOMA** and infected wounds, [Gurewicz] 2007—ab  
nontraumatic spontaneous subaponeurotic, relation to scurvy, [Scott] \*348  
**HEMATOPOIESIS:** See Anemia, Pernicious; Blood forming organs  
**HEMATOXYLIN** Iron - aniline - blue staining method, [Koneff] 1669—ab  
**HEMATURIA**, diagnosis of diseases causing, [Bechtold] 385—ab  
use of quinine in presence of blood in urine, 57  
**HEMATROPHY:** See Atrophy  
**HEMIDIAPHRAGM**, Paralysis (Therapeutic): See Nerves, subclavian  
**HEMIDEMA:** See Edema  
**HEMIPLEGIA**, hemiplegia in, [Luhau] 907—ab  
**HEMOCLASTIC CRISIS**, hemolytic shock, [Woytek] 629—ab  
hemolytic shock after transfusion, [DeGowin] 605—C  
hemolytic shock, Hesse-Filatov treatment, [Eljasovic] 883—ab  
**HEMOGLOBIN:** See also Methemoglobinemia  
in hypochromic anemia before and after gastrectomy, [Kellogg] 311—ab  
in premature and twins vs. full-term infants, [Stewart] 1761—ab  
increasing by iron ammonium citrate, 1407  
production, in anemia vs. infection and intoxication, [Rohschielt-Robbins] 385—ab  
regeneration and chlorophyll, [Hughes] 829—ab  
**HEMOGLOBINURIA** fever: allergic phenomenon, [Fernán-Núñez] 2000—ab  
**HEMOLYSIS:** See Jaundice, hemolytic  
**HEMOLYTIC SHOCK:** See Hemoclastic Crisis  
**HEMOPHILIA**, antiplatelet serum in, [Toeanins] 1005—ab  
bone marrow in, [Jaffé] \*129  
diagnosis, differential, from arthritis, [Kerr] 536—ab  
teeth extraction in, 375  
**HEMOPNEUMOTHORAX**, [Elkin] \*182  
**HEMOPTYSIS:** See also Tuberculosis, Pulmonary  
grave, due to sequestrum of ribs migrated to lung, [Amorim] 468—ab  
**HEMORRHAGE:** See also Brain; Diathesis; Hemorrhagic; Nose; Peptic Ulcer; Prostate; Skin; Stomach; Throat; Uvula; etc.  
allergy, 1825  
chlorophyll converted to hemoglobin after, [Hughes] 829—ab  
infected wounds and bloody effusions, [Gurewicz] 2007—ab  
Subarachnoid: See Meninges hemorrhage  
treatment, ceritamic acid and liver, [Dreyfus] 84—ab  
treatment, cobra and snake venom, 153; [Macht] 813  
treatment, congo red, 1409  
treatment, continuous transfusion, [Wood] 1343—ab  
treatment, Kephrene Hydrochloride, 282  
**HEMORRHOIDS** nostrum, Parana maté and Psyllides, 605—B  
**HEMORRHAGE:** See Hemorrhage, treatment  
also Serotherapy  
cerebral hemorrhage, 545—ab

- HEMOTHERAPY**—Continued  
autiohemotherapy in pediatrics, [Kellhammer] 468—ab  
injecting gravid blood in habitual abortion, [Juag] 2095—ab  
refusion of blood accumulating in abdomen, [Hajak] 1597—ab  
Reaction: See  
ion time, [Heden-  
ius] 210—ab  
sedimentation reaction with, [Enocksson] 246  
—ab  
**HEPATITIS**: See Liver Inflammation; Rift Valley Fever  
**HEPVISC**, 229—B1  
**HERBS**, sixteenth century Indian Herbal to be published, 723  
tea, Lion Cross, 147—B1  
**HEREDITY**: See also Cancer; Dys trophy, muscular; Foot anomalies; Hand anomalies; Tuberculosis; Urine penicilluria  
Bureau of Human Heredity, 364  
**HERELLE, FELIX**, to direct Institute of bacteriophage, Russia, 1905  
**HEMAPHRODITISM**, hormone treatment, 1911  
spontaneous change of sex, [Halban] 2095—ab  
**HERNIA**: See also Medical Abstracts at the end of letter M  
diaphragmatic incarcerated, [Rövig] 2098—ab  
diaphragmatic incarcerated, diagnosis, [Garot] 627—ab  
diaphragmatic, surgical treatment, [Harrington] 165—ab  
internal, after round ligament suspension, [Michael] \*1293  
of fibrous anteius muscle, living fascial transplant to repair, [Hartzell] \*492  
sliding, injection treatment contraindicated [Gordon & Gordon] \*1110  
treatment, injection, Council report, 1053  
treatment, injection, histologic changes after, [Rice] 1671—ab  
treatment, injection, necrosis of spermatic cord after, [Zelman & Larkowski] \*1558  
treatment, injection, subsequent hernioplasty, [Gordon & Gordon] \*1110  
umbilical, 59  
**HERNIOPLASTY** after injection treatment, [Gordon & Gordon] \*1110  
**HERPES**: See also Dermatitis herpiformis  
etiology; rôle of H substance, 449  
labialis, virus of fever blisters, [Rivers] 460  
—ab  
zoster, differential diagnosis, 525  
zoster oculus, [Him] 1753—ab  
zoster, relation to varicella, [Kundratiz] 918  
—ab  
**HERTZ-GEE'S Disease**: See Cellae Disease  
**HESSE-FILATOV Treatment**: See Hemoclastic Crisis  
**HETEROPHILE Antibody**: See Pneumonia treatment  
**HEYD, CHARLES G.**, A. M. A. President, 1227  
**HICCOUGH**: See Hiccups  
**HICCUPS**, short wave therapy, [Weissenberg] 630—ab  
**HIGH BLOOD PRESSURE**: See Blood Pressure  
**HIGH FREQUENCY CURRENTS**: See Diathermy  
**HILUS Glands**: See Lymphatic System  
Pneumonia: See Pneumonia  
**HIP JOINT**: See also Pelvis  
ankylosis, subtrochanteric osteotomy, [Downing & Morris] \*860  
dislocation (congenital), [Van Corder] 1924  
—ab  
dislocation, operative vs. manipulative treatment, [Kleinberg & Buchman] \*1545  
fractures, treatment in elderly, 449  
synovitis (transitory) in childhood, [Finder] 743  
tuberculosis in children; diagnosis, mortality, treated by fusion and grafts, [Barr] \*1517  
**HIPPUIC ACID Excretion Test**: See Liver function  
**HIRSCHFELD'S Method**: See Reticuloeytes  
**HIRSTISM**: See Hair  
**HISTAMINE Injection**: See also Rheumatism  
injection, headache after, [Clark] 162—ab  
reaction of capillaries to, in hypertension, [Dicker] 1843—ab  
Treatment: See Cold sensitivity; Rheumatism  
**HISTIDINE in Urine**: See Pregnancy, diagnosis  
Monohydrochloride: See Bronchiectasis; Colitis, ulcerative; Lung abscess; Peptic Ulcer  
**RIVES**: See Urticaria  
**HOARSENESS**, clinical significance, [Wagers] 2161—ab  
**HODGKIN'S DISEASE**: See Lymphogranuloma; Medical Abstracts at the end of letter M  
**ROFFMANN-WERDNIG Disease**: See Atrophy  
Flu: See Swine Influenza  
herders, disease, 226  
source of undulant fever, [Hardy & others] \*359  
**ROG CHOLERA**, salmonella sulpestifer not cause, [Murray] 809—C; [Mohler] 1739—C  
**HOLMES Syndrome**: See Thalamus  
**HOLMES-ADIE SYNDROME**: See Pupils  
**HOLMSPRAY ATOMIZERS**, 791  
**HOOLOCAINE**, [Lundy] \*1465  
**HOME**: See Housing; Physicians' Home  
**HOMOEOPATHY**, Maryland report, 526  
**HONEY** in infants diet, [Farioli] 393—ab  
**HOOKWORM INFESTATION**, fight on ancylostomiasis, Netherlands, 1981  
treatment, tetrachlorethylene, Council report, 1132  
**HORDER, Lord**, (strain of modern civilization) 1480; (mental police in mad Europe) 1821  
**HORMONES**, Chromatophorotropic: See Chromatophorotropic  
in tumors, demonstrating, [Lewis] 2001—ab  
Male: See Androgens  
Sex: See Androgens; Estrogens; Gonadotropic Principles; Sex; etc.  
**HORNER'S SYNDROME**, 40—E  
**HORSE Serum**: See Serum  
Serum Reaction: See Anaphylaxis and Allergy  
**HORSLEY, JOHN SHELTON**, portrait, 1645  
**HOSPITALS**: See also Clinics; Medical Abstracts at the end of letter M  
Allegheny General, Pittsburgh, 138  
American Hospital Association (meeting), 975; (conference on statistics) 1728; (Rosenwald gift to study insurance) 1817  
approved by A. M. A. \*693; \*703; 738; 1409  
approved, performance of autopsies in, \*669  
bequests and donations, 290; 800; 1231; 1572; 1820  
Care: See also Hospitals, service  
care of premature babies, minimum requirements for, [Hess] \*401  
Charité, historical notes, 142; 2144  
Charity, New Orleans, to be rebuilt, 1570  
children's, for neurologic and behavior disorders, [Bradley] \*650  
children's, Rio de Janeiro, 444  
city, New York, (8 hour day) 45; (positions under Civil Service) 289; (overcrowded) 798  
Cook County, therapy, [Fantus] (psychoanalysis by Kralnes) \*379; (serum reactions by Feinberg) \*1717  
Crippled Children's, New York, 1230  
for Indians, U. S., 1479  
for Joint Diseases, staff appointments available, 1571  
general, teaching psychiatry in, [Billings] \*635; [Christian] 2069—C  
Group Hospital Service, St. Louis, [Seelig] \*359  
Huntington Memorial, huge x-ray machine at, 1815  
Insurance, Rosenwald Fund gift to study and develop, 1817  
Insurance (social) law does not permit choice of, France, 2062  
Internship: See Internship  
laboratory, organization, [Wells] \*1351  
Manhattan General, moves patients to new location, 594  
maternity, for tuberculous, 982  
maternity, liability for puerperal fever, 1312  
maternity ward and streptococcus carrier, 151  
military, surgery in, 1484  
Nurses: See Nurses  
Philadelphia General, ex-residents' dinner, 1644  
proprietary, endorsement, New York, 1309  
psychiatric, new unit, Cal., 2055  
psychiatric, survey of neurosyphilis at Boston, [Moore & Merritt] \*1292  
Revolutionary War, reconstructed, 1898  
Service: See also Hospital care  
service advisers on, New York, 220  
service, Chicago Hospital Council plan, 1569  
service for dependent families; Rochester, N. Y., [Appelbaum] \*1565  
service (group), St. Louis Medical Society plan, [Seelig] \*359  
State: See also Tuberculosis, hospital  
state, at Elgin, expansion, 720  
taxation, Japan, 805  
United Hospital campaign, 1477  
Veterans' Administration to build, 800  
Voluntary Hospitals Commission and the B. M. A., 440; 1304—E  
Wesley (Chicago), Jones's gift to, 1394  
**HOT Climate**: See Tropics; Weather  
Flushes: See Menopause symptoms  
**HOUSE Flies**: See Flies  
**HOUSING**, stum clearance, England, 1729  
**HUDSON, E. H.**, Bejel—nonvenereal syphilis, 793—E  
**HUXNER Cervix Test**: See Uterus  
**HUMERUS**, epiphyseolysis in distant end ns birth injury, [Chatri] 1765—ab  
fracture (supracondylar), 2142  
fracture (supracondylar), arteriotomy for Volkmann's contracture after, 512  
tumors, malignant, radical resection with bone graft replacement, [Albee] \*1693  
**HUMIDITY**, humidification in sinus disease, 2074  
**HUNGARIAN Cancer Committee**, Dollinger program, 601  
**HUNGER**: See also Fasting  
nature of, 1716—ab  
**HYDROCARPUS wightiana oil**: See Leprosy treatment  
**HYDRAMNION**, acute, pathogenesis in twin pregnancies, [Gachetens] 1932—ab  
**HYDRASTIS**, oxytocic drugs, [Davis & others] \*264  
**HYDROCHLORIC Acid**: See Acid  
**HYDROGEN sulfide**, antidote against toxic metals, [Strzyzowski] 391—ab  
sulfide, skin permeability to, 1722—E  
**HYDROLOGY**, International Congress for (fourteenth), 47; 510  
**HYDROPHILIA**: See Water metabolism  
**HYDROPHOBIA**: See Rabies  
**HYDROQUINONE**, staining nerve fibers by silver reduced with, [Bodlau] 160—ab  
**HYDROXIDE**: See Sodium hydroxide  
**HYDROXYESTRIN Benzoate**: See Estrogens  
**HYGIEA**: See American Medical Association  
**HYGIENE**: See also Health; Sanitation  
college, Second National Conference on, 46; 1977  
congress, twenty-third annual, Paris, 1732  
German Society of, founded, 2063  
Industrial: See Industrial  
Institute of, Moscow, 1905  
Mental: See Mental Hygiene  
of sport, 48  
Social: See Social Hygiene  
**HYPERESTHESIA** of skin, neuropsychiatric diagnosis, 608  
segmental neuralgia (radlenoganglionitis), [Davis] \*1620  
**HYPERHIDROSIS**: See Sweating  
**HYPERINSULINISM**: See Insulin; Pancreas secretion  
**HYPERNEPHROMA**, relation to renal adenomas, [Trinkle] 1499—ab  
**HYPEROSTOSIS**: See Cranium; Frontal Bone  
**HYPERPARATHYROIDISM**: See Parathyroid  
**HYPERPYREXIA**: See Fever, therapeutic; Paralysis, General, of Insane; Syphilis, treatment  
**HYPERTENSION**: See Blood Pressure, high  
Ocular: See Eyes, tension  
**HYPERTHERM Kettering**: See Fever, therapeutic  
**HYPERTHYROIDISM**: See also Goiter, Exophthalmic  
acid secretion of stomach in, [Sylla] 88—ab  
blood cholesterol determinations vs. basal metabolic rates in, 1073  
cardiac complications, operative results, 1231  
pregnancy and, [Bodausky] 1166—ab  
thyroid pyramidal lobe in, [Belby] 1508—ab  
treatment, vitamin A, [Abell] 2091—ab  
treatment, x-ray, 1355  
**HYPERTRICHOSIS**: See Hair  
**HYPERTROPHY**: See also Breast; Heart enlargement; Muscles; Prostate; Pylorus; Stomach mucosa; etc.  
osteoporostosis and, new syndrome, [Roy] 302—ab  
**HYPERVENTILATION**: See Respiration  
**HYPNOTICS**, use of, [Grabfield] \*1381; [Wells] \*2104  
**HYPNOTISM**, use in labor, [De Lee] 1714—ab  
**HYPOCHLORITES**, hot, of low alkalinity in destroy tubercle bacillus, [Costigan] 1081—ab  
Sodium: See Sodium; Sporotrichosis  
**HYPOCHONDRIASIS**, [Brown] 2091—ab  
**HYPODERMIC Needle**: See Needle  
**HYPOGLYCEMIA**: See Blood sugar  
Insulin Shock: See Dementia Praecox, treatment  
**HYPOHYDRATION**, fluid postoperatively, [Fantus] \*14  
**HYPOPARATHYROIDISM**: See Parathyroid  
**HYPOPHYSIS**: See Pituitary  
**HYPOSPADIAS**, [Young] \*1448  
rarely cause of sterility, 1326  
**HYPTHYROIDISM**, blood cholesterol determinations vs. basal metabolic rates in, 1073  
**HYSTERIA**, persistent yawning, 2152  
**HYSTEROSALPINGOGRAPHY**: See Uterus, roentgen study  
**I.**  
**I.Q.**: See Intelligence Quotient  
**I.V.C. Habbat Liver Oil**, 1303  
**ICE CREAM**, Gridley Chocolate, 131  
**ICTERUS**: See Jaundice  
Index: See Blood bilirubin  
**IDE Reaction**: See Syphilis serodiagnosis  
**IDENTIFICATION**: See Cancer cell  
**IDIOCY**, mongolism in one of dizygotic twins, [Jenkins] 385—ab  
mongolian, never repeats in same family, 2075  
**IDIOSYNCRASY**: See Anaphylaxis and Allergy  
**IGOL Oral and Igol G. U.**, 659  
**ILEITIS**, regional enteritis (nonspecific), [Meyer] 464—ab  
terminalis, [Knapper] 1934—ab  
**ILEUM**, anastomosis with sigmoid flexure, [Mayo & Wakefield] \*346  
peptic ulcer produced in, [Wu] 1170—ab  
tuberculous tumor, [Cossman] 547—ab  
**ILEUS**: See Intestines obstruction  
**ILLINOIS Association for the Crippled**, created, 1896  
**ILLNESS**: See Disease  
**ILLUMINATION**: See Lighting  
**ILVENTO, ARCANGELO**, death, 1825  
**IMMUNE Serum**: See Meningitis; Serum  
**IMMUNITY**: See also Cancer; Intestines; Polymyositis; Rift Valley Fever; etc.  
virus, mechanism, 976  
**IMMUNIZATION**: See also Diptheria; Measles; Meningitis; Rabies; Tuberculosis; etc.  
with snake venom to produce antivenom, use of taploca in, [Mallick] 625—ab  
**IMMUNOLOGY**: See Asthma treatment

third generation, 810  
treated and untreated in male Negro, [Vonderlehr & others] \*856  
treatment, 607; 1740; [Cole] \*2123  
treatment, adequate, development, [Moore] \*787  
treatment, arsenical (sodium succinylmethylamide-*p*-arsionate), [Yorke] 624—ab  
treatment, arsenic-male exanthems favorable effect on, [Buschke] 835—ab  
treatment, arspenamine-bismuth, articular disorders in, [Gerner] 1164—ab  
treatment, bismuth arspenamine sulfonate, fatal fat embolism after, [Swartz] 75—ab  
treatment, bismuth ethyl camphorate, [Thurmon] 1506—ab  
treatment, bismuth, in arspenamine sensitive patient, 898  
treatment, bismuth (insoluble) compounds, [Hanzlik] 1985—C  
treatment, complicated by functional pruritus, 1243  
treatment, course recommended, 1986; [Cole] \*2129  
treatment, effect of rest on results, [Obermayer] 820—ab  
treatment, fever (electrolytosis) of early stage, 61; [Neymana & others] \*194; [Berris] 732—C; (reply) [Neymann] 732—C; Krusen \*1219; [Slmpson] 1758—ab  
treatment, Friedman's Ready Reference tables, 151  
treatment, intermittent in rural areas, 810  
treatment, mapharsen, 232; (reply) [Schoch] 737; [Kulchar] 1668—ab; [Cole] \*2127  
treatment, mercury, 734  
treatment, natural antisiphilitic healing forces in animals vs. man, 1064  
treatment of early type, 2063; [Cole] \*2129  
treatment of father advisable (with negative Wassermann) whose child has symptoms, 896  
treatment of symptomless, but with positive Wassermann, 898; 899  
treatment of undiagnosed in special department, 443  
treatment, place of nonspecifics in, 295  
treatment, sulfarsphenamine reaction to, 153  
treatment, typharmid, if optic atrophy exists; other treatment recommended, 1656  
treatment, vaccine, with syphilitic antigens, [Vevorovsky] 1516—ab  
treatment, Washington state health department furnishes drugs, 709  
Wassermann fast, 59; [Chargin & Rosenthal] \*1374; [Cole] \*2127  
**SYPHILOLOGY**, American Board of, 1728  
hospitals approved for residences in, \*703  
**SYRINGE**, encephalogram, [Brown] \*1716  
for multiple syringe method (Llademan), [Houck] \*491  
**SYRUP**, brands accepted, 39; 1637; 1719; 1811

roentgenograms, 1146  
use of terms: premolar, mandibular and maxillary, not bicuspid, upper and lower, [Curtis] \*1239  
**TELEPHONE**, dermatitis in cable splicers, [Schwartz] 79—ab  
**TEMPERATURE**: See also Cold; Heat  
in stratosphere, 657—ab  
**TEMPERATURE, BODY**: See also Skin  
High: See Fever  
persistent subnormal, 2074  
premenstrual elevation in pulmonary tuberculosis, [Wellner] 1086—ab  
**TEMPORA**, edema in thyrotoxicosis, [Wahlberg] 1424—ab  
**TEMPORAL BONE**: See also Petrous Pyramid  
facial canal, operative exposure, [Tremble] 384—ab  
**TEMPOROMANDIBULAR JOINT**: See Jaws  
**TENDON** tucker of Bishop, Peters modification, 1327  
**TENNIS** arm, treatment, 522  
**TENT**: See Oxygen  
**TERATOMA**: See Arrhenoblastoma; Testis  
**TERHUNE, ALBERT P.**, on mad dogs, 433—E; [Morris] 809—C; (physiology of fear), 1931  
**TERMINOLOGY**: See also "Words and Phrases" under Medical Abstracts at end of letter M  
bacterial, 214—E  
fibrositis myositis, etc., [Hench] 535—ab  
in Garrison's HISTORY OF MEDICINE, [Nash] 1151—C  
incubation period, 521  
naming of medicaments, recommend International committee, [Heubner] 809—C  
of estrus-producing compounds, Council report, \*1221  
of "male hormones," Council report, \*210  
premaxillary, mandibular and maxillary, not bicuspid, upper and lower, [Curtis] \*1239  
psychiatric definitions, 2074  
"spherocytic jaundice," [Krumhaar] 1739—C  
"sterile," "sterilize" and "sterilization," Council report, 38  
style in medical writing, [Read] 1489—C; [Pusey] 1909—C  
**TERMITES**, toxic effects of dichlorobenzene used to destroy, 607  
toxicity of Osmaltic repellent, 1240  
**TESTIMONIAL**, doctor's, and Diaplex, 42—E  
use in Germany, 600  
**TESTIS**, cancer, diagnosis, [Incapraro] 751—ab  
extracts have no effect in impotence, 1325  
Hormone: See also Androgens  
hormones, nomenclature, \*210  
tumor, adenoma tubular, [Behrend] 1590—ab  
tumor, chorionepithelioma, [Friedländer] 396—ab  
tumor, teratoma, choroidal chorionepithelioma secondary to, [Macdonald] 2084—ab  
undescended, [Gordon] 1758—ab  
undescended, best preparation to hasten descent, 1911  
undescended, gonadotropic substance for, 2071  
undescended or hypoplastic, diet and pregnancy urine extract for, [Dorf] 824—ab  
**TESTOSTERONE**, \*211  
**TEST-TUBE** Babies: See Impregnation  
**TETANUS** antiserum, pneumonia after infection, 1831  
antitoxin (cow not horse) given to sensitive patient, 1243; (reply) [Engelsher] 1493  
antitoxin, neuritis of myelitis after, 1913  
antitoxin, Tetanus Gas-Gangrene Antitoxin, "Globulin-Lederle-Modified", 791  
Antitoxin, Tetanus Gas-Gangrene Antitoxin Mixed-Mulford, 791  
antitoxin, Tetanus-Gas Gangrene Antitoxin (Squibb), 355

## TETANUS—Continued

- antitoxin, universal use, in any wounds, 610; 1491  
cerebrospinal fluid in, 226; [Liberti] 2163—ab  
"home cured" catgut source of, 1143  
thrombocyte and leukocyte pictures in, [Ar-neth] 752—ab  
toxoid, use in sensitive patients, 1408  
treatment, antiserum plus barbitol derivative, [Caminiti] 1596—ab  
treatment, phenol intraspinally, [Grasmlek] 172—ab  
treatment, various drugs, especially tribrom-ethanol, [Freeman] 749—ab  
vaccination obligatory in French army, 1314  
**TETANY** and epilepsy: question of late spasmophilia, [Lindeboom] 1088—ab  
summer, and serum calcium, [Fredeen] 386—ab  
**TETRACHLORETHYLENE**: See tetraChlor-ethylene  
**TEXAS** Girl Brand Baking Powder, 1719  
**TEXTILE MILLS**: See Industrial  
**THALAMUS** syndrome of Head and Moles, neuropsychiatric diagnosis, 608  
**THALASSEMIA**: See Anemia, erythroblastic  
**THAYSEN-GEE'S Disease**: See Feces, fat in  
**THEELIN**: See Estrogens  
**THEEOL**, \*1223  
**THEOPHYLLINE** with ethylene diamine, therapeutic use, [Gell] 918—ab  
**THERAPEUTICS**: See also Hemotherapy; Occupational Therapy; Physical Therapy; Roentgenotherapy; Serotherapy; etc.  
pharmacopoeial substances, [Bastedo] \*780; 794—E  
psychoanalysis in, [Hyman] \*326  
therapy of Cook County Hospital, [Fantus] (psychoneuroses by S. H. Kraines), \*578; (horse serum reactions by Feinberg), \*1717  
**THERMALAID**, 1150—BI; 1405—BI  
**THERM-A-MODE**, 130  
**THIENIA**: See Blood sulfur  
**THIOCYANATE**: See Potassium  
**THIOSULFATE**, Sodium: See Sodium (cross reference)  
**THIRST**, nature of, 1614—ab  
**THOMAS-KINSEY Foundation**: See Foundations  
**THOMSON, D. A.**, fraudulent salesman, 595  
**THORACIC DUCT**, thrombolympangitis, [Pol-layes] \*1379  
**THORACOPLASTY**: See Tuberculosis, Pul-monary  
**THORAX**: See also Hemopneumothorax; Pneumothorax  
intrathoracic pressures, relation to arterial and intrasplinal, [Hamilton & others] \*853  
physiologic effects of correcting faulty posture, [Laplace & Nicholson] \*1009  
reactive chest application, 1324  
readjustments in thoracic cage after pneumonectomy, [Richhoff] 358—ab  
roentgenograms of chest in diagnosis of fat embolism, [Jirka] 1922—ab  
surgery, hospitals approved for residencies, \*114  
thoracoscopy (Jacobus'), [Altshuler] 1597—ab  
wounds of viscera, [Elkin] \*181  
**THORIUM Dioxide**: See Uterus roentgen study  
**THREAD**: See Sutures

Veterans: See Veterans  
**WOUND:** See also Needle; Thorax  
healing, action of vitamins, [Proto] 627—ab  
healing of chronic purulent type, urea to stimulate, [Robinson] 1415—ab  
infected, and bloody effusions, [Gurewlich] 2007—ab  
infected, cod liver oil ointment for, [Hayasli] 543—ab; [Gadomst] 1384  
Penetrating: See Cranium  
subcutaneous emphysema after, 524  
universal use of tetanus antitoxin in, 610; 1491  
**WRITING, Medical:** See Literature  
Prescriptions: See Prescriptions  
**WRY-NECK:** See Torticollis

## X

**XANTHELASMA** of eyelid, [O'Brien & Bracey] \*937  
**XANTHOMATOSIS** (Schüller-Christian's disease), [Strong] \*422  
sudden death and, 1008—ab  
**XERODERMA pigmentosum,** [Macklin] 1838—ab  
**XEROSTOMIA** from x-ray treatment for hypertrichosis, [Greenbaum & Tumen] \*1297  
**XYLOSIS,** injurious effects of hellogravure, 889

## Y

**Y. M. C. A.** anniversary of birth of Sir George Williams, 1231  
**YALE Alumni Association** of, 1641  
**YAWNING,** persistent, 2152  
**YAWS:** See Frambesia  
**YEAST,** special purpose foods, Council on Foods General Decision, 1303  
hay fever and asthma due to, [Felnberg] \*1861  
Milk: See Milk, vitamin D  
**YEISER, CRAIG,** Memorial Fund, 508  
**YELLOW FEVER** diagnosis by liver examination, [Hackett] 544—ab  
viruses, [Hivers] \*207, 460—ab  
**YERBA mate,** nostrum: Parana Mate and Pyalades, 605—BI  
**YPERITE:** See DiChlorodithyisulfide

## Z

**ZABALA, ARTURO,** death, 891  
**ZAMBINI Reaction:** See Saltra  
**ZIEHL-NEELSEN** staining method, modified, [Lange] 631—ab  
**ZINC-Insulin Protamine Treatment:** See Diabetes Mellitus  
ointments, [Fantus] \*862  
**ZIPPER** trauma of penis, [Susskind] 603—C  
**ZOSTER:** See Herpes Zoster

## AUTHOR INDEX

In this Index are the names of the authors of articles which have appeared in THE JOURNAL, the names of those who have read papers before Societies as published in THE JOURNAL and those whose articles have been abstracted in the Current Medical Literature Department. The \* preceding the page reference indicates that the article appeared in full in THE JOURNAL. For subject index see page 2167.
